## 1 Introduction

This *Geotechnical Design Analysis* presents the results of the geotechnical engineering evaluation performed by Anchor QEA, LLC, to determine the basis of design for the upper reach (river miles [RMs] 3.0 to 5.0) of the Lower Duwamish Waterway (LDW) Superfund Site in King County, Washington. The remedial actions associated with the upper reach include dredging and capping of areas within the waterway, including areas that have waterfront or overwater structures; placing thin cover of clean material for enhanced natural recovery (ENR); and backfilling dredge areas within elevation ranges that support habitat as described in the Final (100%) Remedial Design (RD) *Basis of Design Report* (BODR) to which this *Geotechnical Design Analysis* is an appendix.

## 1.1 Locations Studied

The proposed work requires remediation within the actively managed federal navigation channel (FNC), areas adjacent to waterfront and offshore structures, and early action areas (EAAs) over a range of subtidal and intertidal elevations. Subtidal areas are defined as areas below elevation -4 feet mean lower low water (MLLW). Intertidal areas represent elevations between -4 feet MLLW and the mean higher high water line (MHHW; equal to +11.4 feet MLLW), which horizontally defines the limit of sediment cleanup actions in the upper reach. The MHHW line occurs along sloped embankments or vertical bulkheads. Upland areas are locations above MHHW that abut and include shoreline property where buildings and structures may be encountered.

## 1.2 Report Structure

This Geotechnical Design Analysis includes the following six main sections:

- Section 1 is the introduction.
- Section 2 discusses the subsurface conditions underlying the site in more detail than
  presented in the *Pre-Design Investigation Data Evaluation Report* (DER) (Anchor QEA and
  Windward 2022); this section also describes the soil engineering parameters assigned to the
  major stratigraphic units.
- Section 3 describes the geotechnical engineering analyses performed for each of the following design elements:
  - Dredge prism side slope stability
  - Bank side slope stability
  - Cap bearing capacity and settlement evaluations
  - Backfill design
- Section 4 presents geotechnical engineering recommendations to be used by the structural engineer for the assessment of the following:
  - Bulkhead design, including lateral earth pressures and tieback design soil parameters
  - Pile design, including vertical and lateral pile capacity

- Section 5 discusses seismic (earthquake) evaluations for the site.
- Section 6 presents references that were used to support this work.

Attachments to this Geotechnical Design Analysis include the following:

- Attachment G.1 Subsurface Investigation Program and Field Logs
- Attachment G.2 Geotechnical Laboratory Testing
- Attachment G.3 Supplemental Geotechnical Information by Others
- Attachment G.4 Calculations

## 2 Subsurface Geotechnical Conditions

Subsurface geotechnical conditions at the site were investigated by Anchor QEA to supplement the existing geotechnical information that was collected during past projects in the vicinity of the upper reach. Details regarding these prior investigations can be found in the DER (Anchor QEA and Windward 2022).

Subsurface geotechnical conditions in the upper reach of the LDW were investigated by Anchor QEA as part of the Phase I and Phase II pre-design investigation (PDI) efforts completed in 2021 and 2022. The geotechnical PDI included the following numbers and types of geotechnical investigations, which were advanced to a range of depths below ground surface:

- 29 rotosonic borings
- 20 cone penetrometer tests (CPTs)
- 5 vane shear tests (VSTs)
- 7 full-flow penetrometer (FFP) tests
- 2 hand auger borings
- 2 dynamic CPTs

The locations of these geotechnical investigations are presented in Figures G1-1a and G1-1b. Logs from these investigations are presented in Attachment G.1, and geotechnical laboratory testing results are presented in Attachment G.2.

The scope of the geotechnical PDI was developed considering existing geotechnical information within the upper reach. Studies by others provide supplemental subsurface geotechnical data in upland areas adjacent to the upper reach and at in-water locations. Attachment G.3 presents the locations with supplemental geotechnical information and lists the studies that have been identified as providing useful subsurface geotechnical data in the upper reach.

The following sections provide a more comprehensive discussion of subsurface conditions encountered at the site than is presented in the DER.

## 2.1 Subsurface Stratigraphy

BODR Section 8.2 summarizes the stratigraphy. The following section provides more detailed information on the geotechnical properties for the three major stratigraphic units described in the DER (Anchor QEA and Windward 2022) and the BODR for the purposes of geotechnical engineering design and analysis later described in this report.

## 2.1.1 Fill

Fill soils were encountered at two locations during the Phase II PDI and at several other upland locations investigated by others. The specific geologic interpretation of fill is indicated on historical boring logs from Boeing Plant 2, both the east and west banks at the South Park Bridge, and at several properties that are not adjacent to remedial action level (RAL) exceedance areas (e.g., near RM 3.0 west and between RMs 3.5 and 3.6 west at Terminal 117 [T-117]). Given the river history of channelization, fill is likely present along many banks of the upper reach that have not been geotechnically investigated.

Generally, the fill material had been placed to regrade the existing fluvial plain created by the Duwamish River to support shoreline development and re-channelization of the LDW. The unit weight of this material is assumed to vary, but, to prepare design recommendations, the material is assumed to be conservatively represented by an overall average value of 135 pounds per cubic foot (pcf) based on laboratory direct shear test results. Grain size distribution tests show that this material is predominately sand with varying amounts of silt. In areas where fill was more randomly placed, it would be expected to contain anthropogenic materials such as debris, which would be typical of historical shoreline development filling activities in active industrial areas. The moisture content in the fill unit generally ranges from 6% to 28%. Direct shear testing of the fill indicates a peak friction angle average of 36 degrees and a residual friction angle average of 33 degrees.

The findings associated with the two upland borings completed in 2021 are in general agreement with historical investigations completed by others.

## 2.1.2 Recent Sediments

Recent sediments are defined as material that has deposited on top of the alluvium layer and are distinctly characterized by finer gradation and soft consistency compared to the alluvium layer below. Recent sediments were encountered throughout the intertidal and subtidal areas, having been naturally deposited by flows to the LDW upper reach from Green River upstream. The thickness of this unit across the site varies widely and is observed to be thickest in areas of historical dredge activities in the FNC and Slip 6.

Based on a review of laboratory testing results, a total unit weight of 100 pcf was assumed to best represent average overall conditions, with percent moisture content ranging from 34% to 97%. Atterberg limits (plasticity) testing indicates that this material is typically non-plastic to very low plasticity, an indication that the finer fractions are predominantly silt rather than clay. Direct shear testing indicates a peak friction angle of 34 degrees for the recent sediments and a residual friction angle of 33 degrees, whereas VST and FFP testing indicate undrained shear strengths ranging as shown in Figure G2-1. Grain size analyses indicate that this material is approximately 30% sand and 70% silt and clay, with silt content ranging from 22% to 62% and clay content ranging from 2% to 7%.

## 2.1.3 Alluvium

Investigations prior to the PDI describe the alluvium by referencing an upper alluvium unit and a lower alluvium unit. Because the distinction between the upper alluvium and lower alluvium is not important in the context of the sediment cleanup, in the DER, the description of the alluvium was simplified by combining the upper alluvium and lower alluvium into a single alluvium unit, recognizing that there are some gradational changes in the alluvium with depth (Anchor QEA and Windward 2022). Alluvium was observed to underly the recent sediments and be predominately coarse-grained material with pockets, lenses, and layers of silt and clay. Silt content of the fine-grained layers was as high as 76%, and clay content was as high as 16%; silt and clay content was observed to be as low as 1.5%. The alluvium unit has a typical specific gravity of 2.5 to 2.7; is non-plastic; and has a typical total unit weight of 125 pcf, a measured peak friction angle ranging from 32 to 40 degrees (average 37 degrees), and a measured residual friction angle ranging from 28 to 37 degrees (average 32 degrees).

#### 2.2 Groundwater and Surface Water Elevations

Groundwater and surface water affect the geotechnical behavior of soils and sediments. Water surface elevations are used in geotechnical engineering evaluations to calculate porewater pressures and effective stresses, which govern the shear strength of soils. Changes in effective stress (which occur due to changes in porewater pressure) also lead to consolidation settlement. Thus, water surface elevations are a key input parameter for geotechnical engineering evaluations. This section summarizes general observations of groundwater and surface water levels made during the geotechnical investigation and as summarized in other reports.

#### 2.2.1 Groundwater

Groundwater has been observed in shoreline groundwater wells along the upper reach. At locations nearest the LDW, groundwater elevations vary regularly in accordance with the water level in the river. Farther from the shoreline, groundwater levels are less affected by the adjacent surface water level but are still expected to vary seasonally. Table G2-1 summarizes typically observed groundwater levels at selected locations along the upper reach for exploration locations adjacent to the LDW, which are used as a basis for geotechnical engineering evaluations described in this report.

Summary of Selected Ground	Summary of Selected Groundwater Levels for Exploration Excations Aujacent to the EDW						
Location	River Mile	Observed Groundwater Elevation Range (feet above MLLW)	Observed Depth to Groundwater Range Below Ground Surface (feet)	Reference

# Table G2-1 Summary of Selected Groundwater Levels for Exploration Locations Adjacent to the LDW

Note:

LDW: Lower Duwamish Waterway MLLW: mean lower low water SPU: Seattle Public Utilities T-117: Terminal 117

## 2.2.2 Surface Water

The upper reach is tidally influenced, and water levels are also affected by inflows from Green River upstream. Upstream inflows are controlled by the Howard Hansen Dam, so tidal influences tend to dominate the river stage (surface water elevation) on a daily basis. In the project vertical datum, the MHHW elevation is 11.3 feet, and the MLLW elevation is 0 foot.

## 2.3 Soil Engineering Modeling Parameters

This section summarizes the geotechnical engineering properties that were assigned to each lithologic unit for geotechnical evaluations. Engineering properties were derived using correlations to in situ CPT results, VST results, FFP test results, and geotechnical laboratory testing results. For cap aggregates, habitat materials, and backfill, engineering parameters were assigned using best professional judgment and from past project experience considering the location of placement (beneath the water surface) and the typical materials used for these applications (sand and gravel). Soil parameters are presented in Table G2-2.

			Undrained Shear Strength <sup>1</sup>		Drained Shear Strength	
Soil Layer	Total Unit Weight (pcf)	Cohesion (psf)	Internal Friction Angle, φ΄ (degrees)	Cohesion (psf)	Internal Friction Angle, φ΄ (degrees)	Compression Ratio (unitless)
Fill	135	N/A	N/A	0	33	See Note 2
Recent sediments	100	10+38*Z; ≤200	0	0	27	0.17
Alluvium	125	100+30*Z; ≤1800	0	0	32	0.09
Cap, habitat and backfill materials	110	N/A	N/A	0	32	See Note 2
Armor Rock	135	N/A	N/A	0	40	See Note 2

#### Table G2-2 Soil Parameters for Slope Stability Analysis of Dredge Prism Side Slopes

Notes:

1. Z = depth below top of layer surface elevation

2. The fill, cap, habitat, backfill, and armor rock materials, being primarily granular, were not considered compressible for purposes of consolidation calculations. See discussion of compressibility.

N/A: not applicable. See discussion of undrained shear strength (Section 2.3.1).

pcf: pounds per cubic foot

psf: pounds per square foot

## 2.3.1 Undrained Shear Strength

Undrained shear strength can be directly estimated from the tip resistance measured during advancement of the cone during CPT and FFP testing, allowing for a near-continuous relationship of undrained shear strength versus depth (Robertson and Cabal 2010). For the proposes of this report, undrained shear strength values were determined by inspection of the FFP test and VST results at each location. This inspection was completed by plotting undrained shear strength with depth.

Figure G2-1 presents the measured undrained shear strength with depth. Analysis of this plot shows that the undrained shear strength for the recent sediments, as well as for the compressible layers within the alluvium, increases linearly with depth. Thus, the design assumes undrained shear strength is variable, as presented in Table G2-2. Undrained shear strength is not relevant for cohesionless materials (e.g., sand and gravel), which rely on inter-particle friction to develop strength. Thus, the undrained shear strength for sand and gravel type materials (fill, cap, habitat, and backfill) is not applicable because these materials are not expected to behave in an undrained manner.

## 2.3.2 Drained Shear Strength

Drained shear strength applies to the long-term behavior of fine-grained materials and both the short- and long-term behavior of granular materials, which drain very rapidly under applied loads.

Drained shear strength can be correlated to in situ tests (e.g., standard penetration test blow counts, CPT records) and can be measured in laboratory geotechnical tests.

For this project, a series of direct shear tests was conducted on representative undisturbed samples from each major stratigraphic unit to evaluate drained shear strength behavior in terms of peak and residual friction angles. In general, average peak friction angles ranged from 34 to 37 degrees, and average residual friction angles ranged from 32 to 33 degrees.

Laboratory testing is conducted under ideal conditions and reflects assumed loading rates and drainage conditions that potentially will not apply under full-scale conditions. It is expected that actual soil behavior will be more variable and reflect inherent uncertainty that cannot be captured by laboratory testing alone. Thus, the laboratory test results were reviewed by an experienced geotechnical engineer, who applied engineering judgment to reduce the friction angle (drained shear strength) selected for design to reflect values more typically used regionally in engineering design. See Table G2-2 for a summary of friction angles that were selected for design for each major geologic unit.

## 2.3.3 Compressibility

Consolidation settlement (i.e., compression) occurs over time as new loads are applied to fine-grained soil or sediment and as water is driven out of the soil/sediment pore space due to the applied loading (i.e., drainage).

Compressibility parameters were assessed using the laboratory one-dimensional oedometer consolidation test. The test incrementally loads an undisturbed sample and measures the corresponding settlement, which is plotted as a relationship between stress (load) and strain (settlement). When stress is plotted in log scale and strain in natural scale, the resulting plot is generally linear over the range of virgin compression, and the slope of this line is referred to as the Compression Ratio. The Compression Ratio can be used to calculate anticipated consolidation under load.

Four oedometer tests were conducted: one in the recent sediment unit, two within the sandy alluvium, and one in the silty alluvium. The results of these tests were evaluated to develop the consolidation parameters summarized in Table G2-2.

The time rate of consolidation is affected by the distance that water must travel when drainage is occurring. Through inspection of the CPT porewater pressure profiles, a maximum drainage path  $(H_{dr})$  length of 3.5 feet was determined. Lastly, for the purposes of the analysis for this project, a design coefficient of consolidation of 0.08 square feet (ft<sup>2</sup>) per day was assumed.

## **3** Geotechnical Engineering Analysis

This section discusses the following geotechnical engineering analyses prepared in support of the RD:

- Dredge prism side slope stability
- Bank excavation slope stability
- Cap bearing capacity and settlement

## 3.1 General Dredge Prism Side Slope Stability

Dredge prism side slope stability was evaluated using limit equilibrium methods and confirmed using an alternate method. This section describes the evaluation of dredge prism side slope stability including the following:

- Limit equilibrium model background
- Limit equilibrium model development
- Limit equilibrium method model results
- Alternative method model background, development, and results

## 3.1.1 Limit Equilibrium Model Background

The stability of dredge prism side slopes was evaluated using Rocscience Slide2 limit equilibrium software model. For a given evaluation, a geologic cross section was developed, and soil layers and soil geotechnical engineering parameters were input into the model.

The limit equilibrium model software calculates load (soil stress) and resistance (soil strength) for numerous trial "slip surface" geometries to generate a factor of safety for each trial slip surface. The slip surface with the lowest factor of safety is considered the "critical" slip surface for a particular stability cross section. Slip surfaces are generated using an automated search routine within the software so that an appropriate number of trial surfaces are checked when identifying the critical slip surface. The calculation method (General Limit Equilibrium) satisfies both force and moment equilibrium for each trial slip surface.

Acceptable (i.e., target) factors of safety are as follows, in accordance with a common U.S. Army Corps of Engineers (USACE) reference for slope stability (USACE 2003):

- Short-term 1.3 or greater
- Long-term 1.5 or greater
- Rapid drawdown 1.3 or greater

The short-term case represents conditions during construction (e.g., for a temporary dredge cut slope prior to backfilling). The long-term case represents conditions once construction is complete (e.g., for backfilled slopes) and soils/sediments have equilibrated to the stress conditions associated with the post-construction slope geometry.

The rapid drawdown condition represents a stability case where changes in water levels along shoreline banks occur when the tide is receding, but adjacent upland water levels have not equilibrated to river water levels. A range (1.1 to 1.3) of acceptable factors of safety is published for the rapid drawdown case in USACE (2003). The high end of the range (1.3) was selected for this evaluation because upland water surface elevations are considered to be more akin to the maximum storage pool case than the maximum surcharge pool case.

## 3.1.2 Limit Equilibrium Model Development

An assumed dredge cut slope and sediment properties (Table G2-2) were input to the limit equilibrium model, and a search routine was run by the software to locate the critical slip surface. Table G3-1 summarizes the factors of safety calculated in this evaluation.

Stability was evaluated for existing slopes and a range of potential dredge slopes for both short-term (undrained) and long-term (drained) conditions.

Based on bathymetric survey conducted during the PDI, the natural angles of the subtidal to nearshore slopes range from 4 horizontal to 1 vertical (4H:1V) to 17.5H:1V.

The limit equilibrium slope stability evaluation was conducted for two different assumed slope cut angles (2H:1V and 3H:1V) and assuming water levels that correspond to both intertidal and subtidal slopes. For the subtidal evaluation, the dredge cut slope was assumed to be entirely submerged. For the intertidal evaluation, the water level was assumed to be 2 feet below the top of the dredge cut slope.

For the rapid drawdown evaluation, it was assumed that the top of the slope on the upland side of the dredge cut would be fully submerged, and a low tide condition (water level 0 feet MLLW) was assumed on the river side of the dredge cut. It was also assumed the slope itself would not drain during the tidal cycle; thus, undrained shear strength parameters were assumed for the dredge cut slope. The rapid drawdown condition was assessed for intertidal slopes only, where water levels within the slope would be changing. For submerged slopes, the dredge cut would be sufficiently distant from the influence of upland water levels to affect the slope stability factor of safety during changing tides.

## 3.1.3 Limit Equilibrium Method Model Results

Table G3-1 summarizes the results of the dredge cut slope stability evaluation for the short-term, long-term, and rapid drawdown cases.

Table G3-1				
Limit Equilibrium Method Factors of Safety	y Summar	y for Dred	ge Cut Slo	pe Stability

Dredge Cut	-				of Safety
Thickness (feet)	Scenario	Target Factor of Safety	Side Slope	Subtidal Slope <sup>1</sup>	Intertidal Slope <sup>2</sup>
	Short-term	1.3	2H:1V	4.2	2.1
	Short-term	1.5	3H:1V	5.3	2.5
5	long torm	1.5	2H:1V	1.1	N/A
5	Long-term 1.5	1.5	3H:1V	1.6	N/A
	Rapid	1.3	2H:1V	N/A	2.1
	drawdown		3H:1V	N/A	2.5
	Chart tarma	1 0	2H:1V	4.5	2.4
	Short-term 1.3		3H:1V	5.0	2.6
7		1 5	2H:1V	1.0	N/A
7	Long-term	Long-term 1.5	3H:1V	1.6	N/A
	Rapid	1.2	2H:1V	N/A	2.4
	drawdown	1.3	3H:1V	N/A	2.6

Notes:

1. The rapid drawdown case does not change conditions for the subtidal slopes because all water surfaces are above the submerged slope and the submerged slope is sufficiently distant from the influence of upland water surface conditions; thus, there is no need for a rapid drawdown evaluation of subtidal slopes created by dredging.

2. Intertidal dredge areas will be backfilled in the long-term condition in accordance with the ROD (EPA 2014); thus, there is no long-term intertidal slope condition created by dredging.

H:V: horizontal to vertical (ratio)

N/A: not applicable

ROD: Record of Decision

In the short-term condition (i.e., during construction), temporary cut slopes of 2H:1V meet the target factor of safety in both subtidal and intertidal areas.

Long-term slopes constructed at 2H:1V do not meet target factors of safety for subtidal dredged slopes. Long-term subtidal slopes constructed at 3H:1V do meet target factors of safety. In intertidal areas, dredge cut slopes will be backfilled, so there is no need to assess long-term dredge cut stability in these areas.

Conclusions for the rapid drawdown stability assessment are the same as the short-term stability assessment.

Based on the slope stability evaluation, short-term dredge cut slopes of 2H:1V can be used for the temporary scenario prior to backfilling. For long-term dredge cut slopes (i.e., areas that will not be backfilled), 3H:1V slopes should be used.

## 3.1.4 Alternative Method Model Background, Development, and Results

As required by the U.S. Environmental Protection Agency (EPA), the conclusions of the limit equilibrium modeling method were checked using an alternative method of assessment—specifically slope stability chart solutions, as presented in USACE (2003) Appendix E.

Table G3-2 compares the chart solutions with the limit equilibrium solutions (Table G3-1) for the short-term (undrained) case and a 5-foot-deep dredge cut. As demonstrated by Table G3-2, the limit equilibrium method used provides a more conservative result; therefore, it is being carried forward as the appropriate tool for assessing slope stability. Attachment G.4 provides a copy of the hand calculations.

Case	Alternative Method (Chart Solution) Factor of Safety	Limit Equilibrium Method Solution Factor of Safety (Table G3-1)
2H:1V Slope – 5-foot cut depth Subtidal	6.5	4.2
2H:1V Slope – 5-foot cut depth Intertidal	3.6	2.1
3H:1V Slope – 5-foot cut depth Subtidal	8.5	5.3
3H:1V Slope – 5-foot cut depth Intertidal	4.7	2.5

## Table G3-2Slope Stability Comparison – Alternative Method and Limit Equilibrium Method Solutions

Notes:

Comparison for short term (undrained) evaluations H:V: horizontal to vertical (ratio)

## 3.2 Bank Excavation Slope Stability

## 3.2.1 General Bank Slope Stability Considerations

In most locations along the banks of the upper reach, bank excavations will require removal of surficial soils or sediment. Where excavations on banks are on the order of 1 to 2 feet deep, the evaluation of bank excavation slope stability is not warranted because removal of thin cuts will not materially affect the stability of the bank itself. Experience conducting similar work on other shoreline

projects has demonstrated that minor bank excavations (1 to 2 feet deep) can be accomplished without causing slope stability problems. This assumption is reasonable for typical bank conditions and was applied for all thin cut areas for the upper reach but may not be applicable in sensitive areas such as those with low strength soils or visible indications of slope instability.

Bank slope stability is a key consideration for areas where deeper cuts are required at the toe of a bank area or on the bank itself. In these situations, the deeper cut can undermine the toe of the bank and can potentially cause slope instability if not accounted for in the design. The bank adjacent to T-117 (RAA 14/15/16) and the Container Properties (RAA 27) area were identified for location-specific bank slope stability evaluation, as described in this section.

#### 3.2.2 Terminal 117 (RAA 14/15/16)

The Final (100%) RD includes subtidal bank excavation adjacent to T-117 in RAA 14/15/16 (also referred to as SMA 12B). Dredge depths of approximately 20 feet will be required between the toe and top of the slope using a temporary 2H:1V side slope.

Following excavation, an engineered cap will be constructed at the base of the slope, and the subtidal dredge cut slope will be backfilled to reestablish a new slope of 3H:1V. Figure G3-1 depicts the cross section and critical slip surface for the post-dredge (short-term) and post-backfill (long-term) condition for a representative cross section at station 217+40.

Stability analyses were run for the short-term condition (during bank cut) and long-term post-construction condition (including capping and backfill). Because the excavation is entirely subtidal, the rapid drawdown case was not evaluated.

Table G3-3 summarizes the resulting factors of safety for the bank stability evaluation at T-117. Both the short-term and long-term cases have acceptable factors of safety.

Case	Side Slope (H:V)	Target Factor of Safety	Modeled Factor of Safety
Short-term	2H:1V	1.3	2.03
Long-term	3H:1V	1.5	1.93

#### Table G3-3 Slope Stability Results – T-117

Note: H:V: horizontal to vertical T-117: Terminal 117

## 3.2.3 Container Properties (RAA 27)

The Final (100%) RD includes bank excavation along the slopes at Container Properties (RAA 27; also referred to as SMA 5). The existing bank transitions from the upland to an intertidal mud flat, and dredging and excavation will occur on the mud flat and banks, respectively. Dredge cut depths range from 2.5 to 3.5 feet at the toe of bank, and the same minimum thickness cut will be performed on the bank itself at a slope no steeper than 2H:1V. Additional excavation thickness will be added on the bank and at the toe as necessary so that the final reconstructed bank does not raise the bathymetry above pre-construction conditions.

Following excavation, the bank will be reconstructed with layers of sand backfill beneath armor rock, as described in the BODR. Figure G3-2 depicts the cross section and critical slip surface for the post-construction (long-term) condition at Container Properties.

To evaluate the stability of bank cuts, a limit equilibrium model was developed for the most critical stability case—that is, the cross section corresponding to the deepest dredge cut at the toe of bank. Stability analyses were run for the existing condition to check model calibration and assumed input parameters, and for the short-term condition (during bank cut), the long-term post-construction condition (including backfill sand and armor rock), and the rapid drawdown case, which assumes water levels beneath the armor rock near the face of the slope would correspond to MHHW.

Table G3-4 summarizes the resulting factors of safety for the bank stability evaluation at Container Properties.

Case	Side Slope (H:V)	Target Factor of Safety	Modeled Factor of Safety
Existing condition	2H:1V	N/A	1.22
Short-term	2H:1V	1.3	1.33
Long-term	2H:1V	1.5	1.49
Rapid drawdown	2H:1V	1.3	1.29

#### Table G3-4 Slope Stability Results – Container Properties (RAA 27)

Notes:

H:V: horizontal to vertical N/A: not applicable RAA: remedial action area

As demonstrated in Table G3-4, the short-term, long-term, and rapid drawdown stability cases have acceptable factors of safety, indicating that the temporary slope cut of 2H:1V is appropriate and that the long-term armored slope will be stable after construction.

## 3.3 Cap Geotechnical Design Evaluation

The Final (100%) RD includes capping as a remedy technology for the dredge and cap area adjacent to T-117 (RAA 14/15/16) and for the reconstructed shoreline slope at Container Properties (RAA 27). Thus, geotechnical capping evaluations prepared for the earlier design phases were updated to support this Final (100%) RD.

This section describes cap bearing capacity and subgrade settlement evaluations completed for the Final (100%) RD of the upper reach sediment remedy and also describes the cap static stability evaluation. Seismic cap performance evaluations are discussed in Section 5.

## 3.3.1 Bearing Capacity

Bearing capacity caps were evaluated using methods described in *Guidance for In-Situ Subaqueous Capping of Contaminated Sediments* (Palermo et al. 1998). When cap material is placed on the surface of soft sediments, there is the potential for a bearing capacity failure directly through the in situ sediment. The initial cap lift thickness must be thin enough to maintain an acceptable factor of safety under the new loading caused by the weight of the cap.

In typical foundation design problems, a factor of safety of 3.0 is used for calculations wherein there is the potential for structural damage or impacts on human safety. This is the suggested factor of safety presented in the ARCS guidance. However, experience on other capping projects has shown that a factor of safety of 3.0 can be overly conservative when considering cap construction lift thickness. Because life safety and structural foundation stability are not design considerations for caps, and because slope stability evaluations use similar factors of safety, a factor of safety of 1.5 was considered appropriate for use in this analysis for evaluating the cap bearing capacity. Subaquatic cap placement has been successfully demonstrated at other sediment cleanup sites when designed using a bearing capacity factor of safety of 1.5, including the Whatcom Waterway sediment cleanup project (Anchor QEA 2015) and the San Jacinto River Superfund Site Time Critical Removal Action (Anchor QEA 2011).

This analysis evaluates the steady-state, short-term stability of the cap and soft sediments during construction. Once the cap has been placed, consolidation of fine-grained in situ sediments will occur, increasing the shear strength of the sediment. Thus, the long-term stability of the cap against bearing capacity failure will be greater than the short-term stability.

The in situ sediments must have sufficient internal strength to prevent local shear failure. To evaluate this condition, the ultimate bearing capacity was calculated with the Terzaghi equations for local failure (Palermo et al. 1998) using the undrained shear strengths described in Section 2.3:

Equation G3-1 $q_{ult} = \left(\frac{2}{3}\right) s_u * N_c$ where: $q_{ult} =$ ult ultimate bearing capacity of sediment (pounds per square foot [psf]) $s_u =$  $N_c =$ bearing capacity factor (dimensionless) = 5.14 for continuous strip footing (Terzaghi and Peck 1967)

This equation applies to a cap placed on the surface of an entirely cohesive soil with an angle of internal friction,  $\phi'$ , equal to zero. For the caps placed in RAA 14/15/16, at least 4 feet of dredging would be performed before cap placement. Therefore, the shear strength at the 4-foot depth interval is considered appropriate for evaluating cap bearing capacity. Based on the shear strength assumptions presented in Table G2-2, the undrained shear strength of recent sediments below the 4-foot depth interval is 162 psf.

The ultimate bearing capacity was calculated as follows:

$$q_{ult} = \left(\frac{2}{3}\right) 162 * 5.14 = 555 \, psf$$

A factor of safety of 1.5 was used to compute the allowable bearing capacity:

Equation G3-2  $q_{all} = \left(\frac{q_{ult}}{FOS}\right)$ where:  $q_{all} = Allowable bearing capacity (psf)$ FOS = Factor of Safety = 1.5

$$q_{all} = \left(\frac{555}{1.5}\right) = 370 \ psf$$

The initial cap lift thickness that could be supported by the lowest strength in situ sediments at an appropriate factor of safety was calculated using the allowable bearing capacity and the following equation:

**Equation G3-3**  $h = \left(\frac{q_{all}}{v'}\right)$ where: lift thickness h = γ' buoyant unit weight of cap material (pcf) = γ' =  $\gamma - \gamma_w$ total unit weight of cap material (pcf) γ = unit weight of water (64 pcf) =

 $\gamma_w$  = unit weight of water (64 p  $\gamma'$  = 110 pcf - 64 pcf = 46 pcf

$$h = \frac{370 \, psf}{46 \, pcf} = 8 \, feet$$

This analysis, which uses the post-dredge in situ shear strength selected for modeling, indicates that the 4-foot-thick cap at RAA 14/15/16 can be placed while maintaining an appropriate factor of safety for sediment bearing capacity during construction, assuming a dredge depth of 4 feet prior to capping. In this configuration, the post-cap surface would not project above the pre-construction ground surface.

## 3.3.2 Subgrade Consolidation Settlement

Subgrade consolidation beneath the load imposed by a cap was assessed for two different scenarios. In both scenarios, the constructed cap would be placed after dredging, and the post-cap grade would be the same as the pre-dredge mudline elevation. The new loads imposed on the subgrade would be caused by the greater unit weight of cap material than the in situ unit weight of the sediments that will have been dredged. Two scenarios were evaluated for post-cap subgrade consolidation for RAA 14/15/16 reflecting different thicknesses of soft sediment beneath the cap, assuming the sediments and cap are entirely submerged.

Both scenarios assume 4 feet of dredging and placement of a 4-foot-thick cap. In Scenario A, 3 feet of soft sediment are assumed to remain beneath the cap. In scenario B, 11 feet of soft sediment are assumed remain beneath the cap. These assumptions allow for bracketing the results to understand the importance of the post-dredge soft sediment thickness that remains. Table G3-5 summarizes the scenarios evaluated for subgrade consolidation.

# Table G3-5Subgrade Consolidation Modeling Scenarios

Scenario	Pre-Dredge Sediment Thickness (feet)	Dredge Depth (feet)	Post-Dredge Sediment Thickness (feet)	Cap Thickness (feet)	Net Stress Increase (psf)
А	7	4	3	4	40
В	15	4	11	4	40

Note:

psf: pounds per square foot

Subgrade consolidation was calculated according to the following relationship:

Equation G3-4				
$\Delta H = 1$	H  imes CR	$\times \log \left( \frac{\sigma_{vo}' + \Delta \sigma_{v}'}{\sigma_{vo}'} \right)$		
where	:			
ΔH	=	consolidation settlement		
Н	=	consolidating layer thickness		
CR	=	compression ratio of subgrade sediment (Table G2-2)		
$\sigma'_{vo}$	=	in situ vertical effective stress		
$\Delta \sigma'_{v}$	=	net stress increase (Table G3-2)		

Table G3-6 summarizes the results of the subgrade consolidation evaluation.

#### Table G3-6 Subgrade Consolidation Summary

Scenario	Estimated Consolidation Settlement (inches)		
A	2		
В	3		

As shown in Table G3-6, the subgrade in RAA 14/15/16 is predicted to settle approximately 2 to 3 inches after cap placement. The magnitude of settlement is not sensitive to the assumed thickness of soft sediment that could remain beneath the cap.

Subgrades can settle differentially under imposed loads. Differential subgrade settlement would manifest itself as a sloping top surface of the cap. In such cases, the cap thickness would not be affected by differential subgrade settlement; therefore, cap performance would not be compromised. Because cap materials are granular, there is no consolidation settlement within the cap layers themselves, and differential settlement is not a consideration for caps.

The time rate over which consolidation occurs is a function of the distance porewater must travel (drainage path length) and the coefficient of consolidation of the subgrade. Time rate of consolidation was evaluated according to the following equation:

Equat	Equation G3-5					
$T = \frac{c}{H_1}$	$T = \frac{c_v t}{H_{DR}^2}$					
where						
Т	=	time factor = 0.8 for 90% consolidation (Lambe and Whitman 1969)				
Cv	=	coefficient of consolidation (Section 2.3)				
t	=	time to achieve 90% consolidation				
HDR	=	drainage path length (Section 2.3)				

Based on Equation G3-5, it is estimated that subgrade consolidation would be 90% complete approximately 120 days after cap construction.

Subgrade consolidation settlement can confound the interpretation of bathymetric survey results if bathymetry surveys are used to confirm the thickness of caps. When subgrade consolidation settlement occurs, bathymetry comparisons (i.e., isopach mapping) can be incorrectly interpreted as indicating "thinning" of cap material. Therefore, supplemental cap confirmation approaches such as thickness probing would also be included in Long-Term Maintenance and Monitoring Plan (LTMMP) planning to address potential issues associated with subgrade consolidation if caps are to be constructed. If cap thinning occurs, corrective measures could include additional material placement.

## 3.3.3 Static Slope Stability of Caps

The Final (100%) RD includes a cap within the armored revetment to be constructed along the Container Properties shoreline (RAA 27). The cap at Container Properties would be placed following excavation, resulting in a cap surface that generally matches the pre-construction grade or flatter in the capping area. This section describes the static slope stability evaluation at Container Properties (RAA 27) where an intertidal cap would be constructed on the bank.

Cap slope stability was evaluated using limit equilibrium methods. A geologic profile was developed for Container Properties using the soil and sediment geotechnical engineering parameters presented in Table G2-2. The modeling software was set to search for the critical slip surface for any location within the slope at Container Properties.

Figure G3-2 presents the geologic profile for the Container Properties shoreline and depicts the critical slip surface and factor of safety. The factor of safety for the cap is 1.49, which is considered acceptable.

## 3.4 Backfill Design

This section describes the gradation and stability design of backfill materials.

#### 3.4.1 Backfill Gradation

The selection of backfill considers several engineering considerations, including the following:

- Commercially available, natural aggregate materials
- Appropriate proportion of gravel within the aggregate mixture to provide stability to backfill placed on slopes, as evaluated in Section 3.4.2
- Limiting the percentage fines (material that passes the U.S. No. 200 Sieve) to protect water quality by minimizing turbidity during placement

Table G3-7 presents a backfill gradation that achieves these objectives and was assumed for geotechnical analysis. The remedial contractor may identify material that is very similar to this gradation and that may be acceptable for use as backfill. The engineer should review any proposed deviations from this specification and may approve an alternate gradation in consultation with EPA.

#### Table G3-7 Backfill Gradation Specifications

Sieve Size	Percent Passing	
4-inch	100	
2-inch	70 to 100	
U.S. No. 4	50 to 80	
U.S. No. 40	0 to 30	
U.S. No. 200	0 to 5	

In addition to engineering considerations, there may be additional habitat considerations that would be evaluated separately in consultation with EPA. Further, backfill material must meet or be lower than chemical concentration limits that will be defined in the project specifications based on cleanup levels for human health and benthic protection.

## 3.4.2 Backfill Stability

Backfill will be placed in habitat areas (elevations greater than -10 feet MLLW) in accordance with the ROD (EPA 2014). In some dredge areas, backfill may need to be sloped below elevation -10 feet MLLW until it meets the post-dredge surface at depth. This section presents the evaluation of stable backfill slope angles to support the backfill grading design.

Backfill slope stability was evaluated using infinite slope stability theory, in accordance with Duncan and Wright (2005). For this evaluation, the factor of safety for a 3H:1V backfill slope was computed using the following equation:

Equati	on G3	-6	
FOS =	tan (Ø tan (i	<u>')</u> )	
where:		, ,	
FOS	=	Factor of Safety	
$\phi'$	=	backfill friction angle (Table G2-2)	
Ι	=	slope angle	

The factor of safety for backfill placed at a 3H:1V slope is 1.9, which is greater than the target long-term slope stability factor of safety. Thus, a 3H:1V slope angle should be used for the design of backfill slopes.

Where steeper slopes may be needed, armor rock could be used to protect the backfill surface. Shoreline armor has a higher friction angle than sand and gravel backfill and is typically assumed to range from 38 to 42 degrees for angular rock (USDA 1989). Assuming an armor rock friction angle of 38 degrees, slopes of 2H:1V have a factor of safety of 1.6, which is greater than the minimum long-term factor of safety of 1.5. Thus, backfill can be placed on 2H:1V slopes if angular armor rock is used.

## 4 Geotechnical Engineering Recommendations to Support Structural Engineering Evaluations

This section presents geotechnical engineering recommendations to support structural evaluations of vertical structures such as bulkheads and bridge piers, and to design replacement piles that may be needed as part of remedy construction in the upper reach. Necessary structural engineering evaluations were developed for the Final (100%) RD based in part on the recommendations provided in this section.

## 4.1 Vertical Structure Evaluation Geotechnical Recommendations

This section provides recommendations for the structural engineer to use for the evaluation of existing vertical structures adjacent to RAL exceedance areas.

## 4.1.1 Lateral Earth Pressures for Shoreline Structures

The following lateral earth pressure recommendations are provided for structural evaluation of cantilevered shoreline bulkhead walls. This information can be used to assess the need for offsets or other measures if dredging needs to be performed in front of bulkheads.

Lateral earth pressures acting on the bulkhead will depend primarily on the following:

- Fill material placed behind the wall, and the degree of compaction immediately adjacent to the wall
- Flexibility of the wall, and the degree of movement that the wall undergoes
- The presence of any surcharges or concentrated loads adjacent to the bulkhead
- Wall drainage
- Seismic loading

If the bulkhead is permitted to yield such that the top can move laterally at least 0.1% of the bulkhead's retained height when loaded, active earth pressures will develop. If this level of deflection is intolerable, the wall should be evaluated using at-rest soil pressures.

To design for lateral earth pressures, the parameters provided in Table G4-1 should be used. Earth pressures may be computed assuming a triangular pressure distribution applied from the top of the bulkhead to the base of the sheeting, as shown in Figure G4-1. Passive pressures will also be applied in a triangular distribution, from the mudline downward.

Table G4-1	
Bulkhead Lateral Earth Pressure Parameters	

Parameter	Design Value
GWT behind bulkhead	6 feet MLLW
Upland soil effective unit weight above GWT	135 pcf
Upland soil effective unit weight below GWT	71 pcf
Upland soil effective friction angle ( $\phi$ ')	33 degrees
Upland soil cohesion c	0 psf
Waterway sediment effective unit weight above waterline	100 pcf
Waterway sediment effective unit weight below waterline	36 pcf
Waterway sediment effective friction angle ( $\phi'$ )	27 degrees
Waterway sediment cohesion (c)	0 psf
$K_A$ – active pressure coefficient for upland soils – flexible walls	0.29
$K_0$ – at rest pressure coefficient for upland soils – rigid walls	0.46
K <sub>P</sub> – passive pressure coefficient for waterway sediments <sup>1</sup>	2.66

Notes:

1. Passive pressures are presented as ultimate values and do not include a factor of safety.

GWT: groundwater table elevation

MLLW: mean lower low weight

pcf: pounds per cubic foot

psf: pounds per square foot

As noted in Table G4-1, using the passive pressure coefficient provided would result in calculating ultimate passive soil resistance, which would be an appropriate assumption for calculating the potential reduction in passive resistance at the toe of the wall when dredging occurs. Figure G4-1 depicts the pressure distribution for active and passive earth pressure conditions and provides recommendations for temporary tieback no-load zone and tentative tieback adhesion values.

## 4.1.2 Effect of Prohibiting Surcharge Loads Above Bulkheads During Adjacent Dredging

Bulkheads retain soil loads and surcharges in the form of active or at rest lateral earth pressures. These earth pressures are resisted at the toe of the bulkhead by passive earth pressures provided by the sediments in front of the bulkhead. The following discussion evaluates how much of the passive earth pressure is needed to resist surcharge loads alone and the effect to prohibiting surcharge loads

during dredging. This assessment was developed using generalized soil and sediment conditions and thus is applicable to structures throughout the upper reach.

It is assumed that shoreline bulkheads were designed and constructed to support temporary surcharge loads at the top of the bulkheads. Typically, a temporary surcharge of 250 psf (or higher) can be accommodated by marine shoreline structures in good condition. Assuming a bulkhead backfill unit weight of 135 pcf, 250 psf is effectively equivalent to a soil surcharge height of approximately 2 feet.

One way to protect structures during adjacent dredging is to prohibit surcharge loading during dredging. This effectively allows for the "design surcharge capacity" of the wall to be used to offset the temporary loss of passive pressure in front of the wall due to dredging.

To evaluate this factor, the bulkhead adjacent to CenterPoint Properties was selected as a representative example. The bulkhead at this location currently has a retained soil height of approximately 15 feet. The active lateral earth pressure behind the wall (no surcharge) is calculated as follows:

Equation G4-1					
$P_A = \frac{1}{2}$	$\frac{1}{2}K_A\gamma$	$h^2$			
where	2.				
P <sub>A</sub>	=	Active earth pressure resultant force (pounds per foot [lb/ft])			
KA	=	Active earth pressure coefficient for retained soil (Table G4-1)			
γ	=	unit weight of retained soil (Table G4-1)			
h	=	retained height of soil (feet)			

For the CenterPoint Properties bulkhead, the resultant active earth pressure is calculated to be 4,400 pounds per foot (lb/ft).

Adding 1.85 feet of retained height for the surcharge loading condition (equivalent to a retained soil height of 16.85 feet), the active lateral earth pressure is calculated to be 5,560 lb/ft, which means that prohibiting surcharge during dredging could offset the loss of 1,160 lb/ft of passive pressure.

Passive earth pressure is calculated as follows:

Equa	Equation G4-2					
$P_P =$	$\frac{1}{2}K_{P}\gamma$	$d^2$				
where	9:					
$P_P$	=	passive earth pressure resultant force (lb/ft)				
K <sub>P</sub>	=	passive earth pressure coefficient for sediments (Table G4-1)				
γ	=	unit weight of sediments (Table G4-1)				
d	=	depth below mudline (feet)				

For the passive pressure coefficients for sediments presented in Table G4-1, a depth of approximately 5 feet below mudline is required to achieve a passive pressure of 1,160 lb/ft when sediments are submerged (buoyant unit weight providing passive pressure) or approximately 3 feet below mudline when sediments are not submerged (total unit weight providing passive pressure).

Based on this evaluation, for shoreline bulkheads in good condition that were designed to support an upland surcharge of at least 250 psf, prohibiting surcharges during dredging would allow for 3 to 5 feet of dredging to occur while maintaining passive pressure support comparable to the surcharge loading condition with no dredging.

Note that this assessment considers the soil loads only and does not account for the condition of the bulkhead wall nor the stresses in the wall structure that might be imposed by removing passive support during dredging.

## 4.1.3 Effect of Dredging on Passive Pressure

As previously discussed, dredging adjacent to structures reduces lateral toe support (i.e., passive pressure), which can increase the loads on the structure. This section describes the evaluations performed to determine appropriate reductions in passive pressure considering the following:

- Dredge cut slope angle
- Dredge cut depth
- Horizontal offset of dredge cut from the structure

The analyses presented in this section were developed specific to the Recent Sediments material that would be removed by dredging and is applicable to any vertical structure in the upper reach (e.g., bulkheads, bridge piers). To conduct this analysis, the total available passive pressure (no

dredging) was compared to the weight of the passive wedge that would remain after dredging. The reduction factor was calculated as follows:

# Equation G4-3Reduction Factor = $\frac{W_w}{P_R}$ where: $W_w$ $W_w$ =Buoyant weight of passive soil wedge between structure and toe of dredge cut (lb/ft) $P_R$ =Passive earth pressure force for the no dredging scenario calculated at the evaluated depth of dredging (lb/ft)

Offsets of 0, 2, and 4 feet from the structure were considered. A range of dredge depths from 5 to 15 feet deep was evaluated. Dredge cut side slopes of 2H:1V, 1.5H:1V, and 1H:1V were assessed.

Key conclusions from this evaluation, in the form of passive earth pressure reduction factors, are presented in Table G4-2.

#### Table G4-2 Passive Earth Pressure Reduction Factors

Offset Distance	Reduction Factor				
(feet)	2H:1V	1.5H:1V	1H:1V		
0	0.75	0.56	0.38		
2	0.85	0.66	0.48		
4	0.95	0.76	0.58		

Note:

H:V: horizontal to vertical (ratio)

As shown in Table G4-2, when the dredge prism is not offset, the passive earth pressure could be significantly reduced, particularly if the dredge cut is oversteepened beyond the recommended 2H:1V temporary cut slope. Reduced passive pressure increases the risk of damaging structures.

The reduction factors presented in Table G4-2, in conjunction with the earth pressure recommendations in Table G4-1, can be used by the structural engineer to determine recommended structural offsets for dredging.

## 4.2 Pile Design Recommendations

Miscellaneous single piles or dolphin pile groups may need to be removed to accomplish construction. This section presents geotechnical engineering pile design recommendations for the structural engineer's use in designing replacement piles.

Based on discussion with the project structural engineer, replacement piles are likely to be hollow steel pipe piles, which lend themselves to vibratory installation and are capable of supporting the range of loads anticipated for this project. Timber piles are not considered for new installations for the upper reach because timber piles require chemical treatment to prevent decay.

Replacement piles are expected to be primarily laterally loaded. Pile design to resist lateral loads can be accomplished using L-PILE or similar software to assess pile deflection under loading and required depth to fixity below the mudline. Table G4-3 presents recommended L-PILE parameters to model the recent sediments and alluvium.

#### Table G4-3 L-PILE Modeling Parameters

Layer	Effective Unit Weight γ' (pcf)	Friction Angle Φ (°)	Undrained Shear Strength c <sub>u</sub> (kip/ft <sup>2</sup> )	P-Y Curve Model	Spring Constant; K (Es=Kx) k (pci)	Strain Factor; @50% max E &50
Recent sediment	36	27	0.08	Soft clay (Matlock)	N/A	0.020
Alluvium	61	32	N/A	Sand (Reese)	20	N/A

Notes:

ft<sup>2</sup>: square foot kip: one thousand pounds N/A: not applicable pcf: pounds per cubic foot pci: pounds per cubic inch

## 5 Seismic Design

The upper reach of the LDW is located within the seismically active Puget Lowland, a region characterized by bedrock faults and tectonic plate movement and that has a documented history of earthquake activity. Earthquakes occur when energy accumulated during fault or tectonic plate movement is suddenly released over a short time span. The location of energy release, known as the epicenter of an earthquake, can occur at different places in a fault system.

The ground shaking caused by an earthquake can cause loose soils to lose strength as porewater pressure increases. This phenomenon, known as liquefaction, can cause soil movement and ground settlement. Earthquakes can also shake structures and impose loads on structural elements and foundations. Seismic risks are assessed in geotechnical engineering using a variety of tools.

This section describes the seismic design of the sediment remedy for the upper reach with a focus on the anticipated performance of remedial elements (primarily sediment caps) under earthquake loading. This section also provides recommended seismic design parameters for use by the structural engineer, as appropriate.

## 5.1 Seismic Site Class

Seismic behavior is generally assessed by evaluating the relative density of near-surface soils (the upper 100 feet below ground surface). For seismic design, relative density is often characterized by the average shear wave velocity of the soil column, which governs how earthquake energy is amplified or dampened by the near-surface soils. A Washington State-wide study by Cakir and Walsh (undated) summarized measurements of shear wave velocity at different sites across the state, including three locations in the Duwamish River basin near the upper reach. This study identified a typical seismic site class between Class D and Class E based on average shear wave velocities between 131 and 183 meters per second for the Duwamish River area in the vicinity of the upper reach.

## 5.2 Strong Motion Design Input Parameters

For seismic evaluations, earthquake peak ground acceleration (presented as a percentage of the force of gravity) and earthquake magnitude are key input parameters.

The U.S. Geological Survey (USGS) provides internet-based tools that, using mapped locations and seismic site classes, output peak ground accelerations, and earthquake magnitudes for different recurrence interval earthquakes.

For the upper reach sediment remedy, two different earthquake types were considered:

- A 100-year recurrence interval earthquake, consistent with typical protectiveness evaluations for other remedy elements such as cap contaminant modeling
- A 475-year recurrence interval earthquake, which has traditionally been the size of event considered on other regional Superfund projects based on a 10% probability of exceedance in a 50-year time frame

Table G5-1 provides the key USGS output parameters used for geotechnical seismic assessment for both events.

# Table G5-1Earthquake Parameters used in Geotechnical Engineering Evaluations

Event Recurrence Interval	PGA (% gravity)	Mean Magnitude	
100 years	0.19	6.7	
475 years	0.41	7.0	

Notes:

Data developed for latitude 47.522, longitude -122.306.

Site Class D/E; Dynamic Conterminous United States model (2014 edition v4.2.0). Model source: https://earthquake.usgs.gov/hazards/interactive.

PGA: peak ground acceleration

## 5.3 Liquefaction Evaluation

As described in Section 2, the site investigation included CPTs at 20 different locations in the upper reach. Digital records from these CPTs were processed by the analytical software Cliq (version 3.3.1.14), which facilitates liquefaction assessment and estimates of liquefaction-induced settlement using CPT measured parameters, earthquake peak ground accelerations, and earthquake magnitude.

For all locations investigated with a CPT, liquefaction was predicted during both the 100- and 475-year earthquakes. The estimated magnitude of liquefaction-induced settlement did not significantly vary between the two earthquakes, ranging from 3 to 14 (median 7) inches of settlement in the upper 30 feet below ground surface.

## 5.4 Seismic Performance of Capped Slopes

The seismic performance of capped slopes was evaluated using limit equilibrium methods, as described for the slope stability discussions in Section 3. A geologic cross section of the slope at Container Properties (RAA 27) was modeled, and seismic forces associated with both the 100- and 475-year earthquakes were added. For the 475-year earthquake, the resulting factor of safety was less than 1.0, indicating that some movement of the capped slope can be expected during a

significant earthquake. For the 100-year earthquake, the factor of safety was 1.15 at Container Properties. Figure G5-1 depicts the cross section evaluated for Container Properties (RAA 27), as well as the critical slip surface and factors of safety for the 100-year earthquake at this location.

In general, shoreline slopes are susceptible to movement during strong earthquake shaking. Slopes designed to resist movement could require significant structural reinforcement that is not compatible with the habitat and human uses of shorelines. In part, due to issues like this, the geotechnical engineering community is moving toward a performance-based assessment of slopes, when appropriate, for seismic design. In the case of shoreline slopes where life safety and structures are not at risk, this type of assessment does not attempt to design for preventing movement; rather, a performance-based approach evaluates how much movement could be expected during an earthquake and what mitigation measures, if any, would need to be implemented after the earthquake had occurred.

Slope displacement was estimated for both the 100- and 475-year earthquakes in accordance with the methods presented by the National Cooperative Highway Research Program (NCHRP 2008). Table G5-2 presents the estimated slope displacement for Container Properties under both earthquake scenarios. Because the cap in RAA 14/15/16 is not on a slope, slope displacement estimates are not applicable.

# Table G5-2Seismic Slope Displacement for Container Properties (RAA 27) Cap

Earthquake Return Interval	Container Properties Cap Estimated Displacement
100 years	< 0.5 inch
475 years	8 to 16 inches

Note:

RAA: remedial action area

## 5.5 Conclusions on Seismic Performance of Sediment Remedy

Based on the liquefaction assessment and slope displacement estimates, the sediment remedy is expected to have acceptable seismic performance. Anticipated settlement and displacement under the 100-year event is expected to be significantly less than any design cap thicknesses. During a larger earthquake, the cap and sediments beneath may move down the slope, but any cap damage from such movement is expected to be easily repaired.

Post-earthquake mitigation measures could include visual inspections and bathymetry surveys to evaluate cap condition. Cap repairs, if needed, could be readily implemented by adding more cap substrate to address any local thinning associated with post-earthquake deformation or settlement.

The LTMMP will consider these evaluations and set criteria for inspections following seismic events.

## PRESENTATION OF SITE INVESTIGATION RESULTS

## LDW Phase 3

Prepared for:

Anchor QEA

ConeTec Job No: 21-59-22445

Project Start Date: 06-JUL-2021 Project End Date: 29-JUL-2021 Report Date: 9-AUG-2021

Prepared by:

ConeTec Inc. 1508 O Street SW, Unit 103-104 Auburn, WA 98001

Tel: (253) 397-4861

ConeTecWA@conetec.com www.conetec.com www.conetecdataservices.com

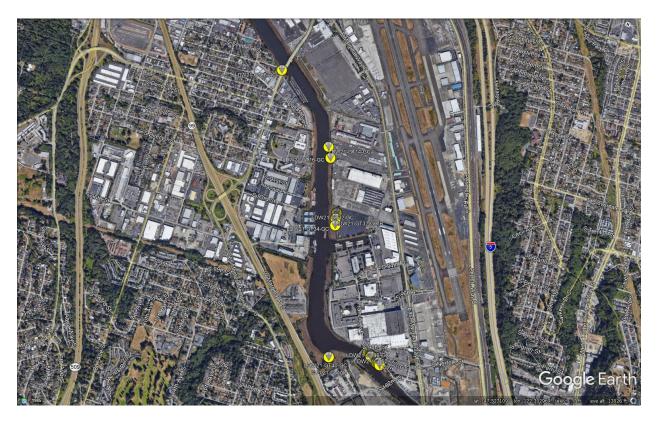

#### Introduction

The enclosed report presents the results of the site investigation program conducted by ConeTec Inc. for Anchor QEA along mile 3-5 of the Duwamish River located in Seattle WA. The program consisted of cone penetration tests, full flow penetration tests & electronic vane testing

#### **Project Information**

Project	
Client	Anchor QEA
Project	LDW Phase 3
ConeTec project number	21-59-22445

An aerial overview from Google Earth including the CPTu test locations is presented below.

Rig Description	Deployment System	Test Type
C05-023 Track Rig	Integrated Push System	CPT, BCPT, VST
A07-018 Amphibious Rig	Integrated Push System	СРТ
Barge Support	Auxiliary Push Boat	CPT, BCPT, VST

Coordinates			
Test Type	Collection Method	EPSG Number	Comments
CPT, BCPT, VST	Client provided	4326	Coordinates converted from State Plane

Cone Penetrometers Used for this Project							
Cone Description	Cone Number	Cross Sectional Area (cm <sup>2</sup> )	Sleeve Area (cm²)	Tip Capacity (bar)	Sleeve Capacity (bar)	Pore Pressure Capacity (bar)	
681:T375F10U35	681	15	225	375	10	35	
Cone 681 was used for all CPTu soundings.							

Cone Penetration Test (CPTu)	
Depth reference	Depths are referenced to the existing mudline at the time of each test.
Tip and sleeve data offset	0.1 meter This has been accounted for in the CPT data files.
Additional plots	<ul> <li>Advanced plots with Ic, Su, phi and N1(60)</li> <li>Soil Behaviour Type (SBT) scatter plots</li> </ul>
Additional comments	A negative water table has been applied to all soundings completed from barge deck. All CPT data files begin at mudline (mudline = 0.0ft)

Calculated Geotechnical Parameter Tables					
Additional information	The Normalized Soil Behaviour Type Chart based on Q <sub>tn</sub> (SBT Q <sub>tn</sub> ) (Robertson, 2009) was used to classify the soil for this project. A detailed set of calculated CPTu parameters have been generated and are provided in Excel format files in the release folder. The CPTu parameter calculations are based on values of corrected tip resistance (q <sub>t</sub> ) sleeve friction (f <sub>s</sub> ) and pore pressure (u <sub>2</sub> ). Effective stresses are calculated based on unit weights that have been assigned to the individual soil behaviour type zones and the assumed equilibrium pore pressure profile.				

Full-Flow Cone Penetration Test (BCPTu)					
Depth reference	All soundings were started slightly above the mudline in the water column. Mudline is clearly indicated on all plots and clearly visible within the data set.				
Unit weight profiles	<ul> <li>A unit weight of 62.43pcf was applied to data collected within the water column above mudline</li> <li>A unit weight of 111.37pcf was applied to data collected below mudline The unit weight is clearly indicated in the data set.</li> </ul>				

Electric Field Vane Shear Test (VST)					
Depth reference	epth reference Depths are referenced to depth below mudline at the time of each test				
Load cell capacity	100 N·m				
Load cell location	Uphole				
Additional comments	All vane tests were completed from the floating barge platform. The vane test results were affected by barge movement from local waves, local vessel traffic and river flow. Additionally, the vane results were susceptible to elevation charge from either rising or falling tide. Over the course of a vane test the barge would gain/lose approximately 2"-4" of elevation due to tidal effects.				

#### Limitations

This report has been prepared for the exclusive use of Anchor QEA (Client) for the project titled "LDW Phase 3". The report's contents may not be relied upon by any other party without the express written permission of ConeTec Inc. (ConeTec). ConeTec has provided site investigation services, prepared the factual data reporting and provided geotechnical parameter calculations consistent with current best practices. No other warranty, expressed or implied, is made.

The information presented in the report document and the accompanying data set pertain to the specific project, site conditions and objectives described to ConeTec by the Client. In order to properly understand the factual data, assumptions and calculations, reference must be made to the documents provided and their accompanying data sets, in their entirety.

Cone penetration tests (CPTu) are conducted using an integrated electronic piezocone penetrometer and data acquisition system manufactured by Adara Systems Ltd., a subsidiary of ConeTec.

ConeTec's piezocone penetrometers are compression type designs in which the tip and friction sleeve load cells are independent and have separate load capacities. The piezocones use strain gauged load cells for tip and sleeve friction and a strain gauged diaphragm type transducer for recording pore pressure. The piezocones also have a platinum resistive temperature device (RTD) for monitoring the temperature of the sensors, an accelerometer type dual axis inclinometer and two geophone sensors for recording seismic signals. All signals are amplified and measured with minimum sixteen-bit resolution down hole within the cone body, and the signals are sent to the surface using a high bandwidth, error corrected digital interface through a shielded cable.

ConeTec penetrometers are manufactured with various tip, friction and pore pressure capacities in both 10 cm<sup>2</sup> and 15 cm<sup>2</sup> tip base area configurations in order to maximize signal resolution for various soil conditions. The specific piezocone used for each test is described in the CPT summary table presented in the first appendix. The 15 cm<sup>2</sup> penetrometers do not require friction reducers as they have a diameter larger than the deployment rods. The 10 cm<sup>2</sup> piezocones use a friction reducer consisting of a rod adapter extension behind the main cone body with an enlarged cross sectional area (typically 44 millimeters diameter over a length of 32 millimeters with tapered leading and trailing edges) located at a distance of 585 millimeters above the cone tip.

The penetrometers are designed with equal end area friction sleeves, a net end area ratio of 0.8 and cone tips with a 60 degree apex angle.

All ConeTec piezocones can record pore pressure at various locations. Unless otherwise noted, the pore pressure filter is located directly behind the cone tip in the " $u_2$ " position (ASTM Type 2). The filter is six millimeters thick, made of porous plastic (polyethylene) having an average pore size of 125 microns (90-160 microns). The function of the filter is to allow rapid movements of extremely small volumes of water needed to activate the pressure transducer while preventing soil ingress or blockage.

The piezocone penetrometers are manufactured with dimensions, tolerances and sensor characteristics that are in general accordance with the current ASTM D5778 standard. ConeTec's calibration criteria also meets or exceeds those of the current ASTM D5778 standard. An illustration of the piezocone penetrometer is presented in Figure CPTu.

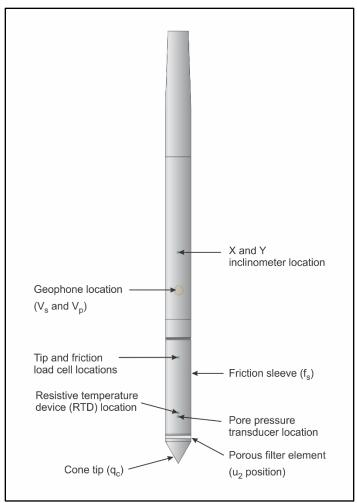

Figure CPTu. Piezocone Penetrometer (15 cm<sup>2</sup>)

The ConeTec data acquisition systems consist of a Windows based computer and a signal interface box and power supply. The signal interface combines depth increment signals, seismic trigger signals and the downhole digital data. This combined data is then sent to the Windows based computer for collection and presentation. The data is recorded at fixed depth increments using a depth wheel attached to the push cylinders or by using a spring loaded rubber depth wheel that is held against the cone rods. The typical recording interval is 2.5 centimeters; custom recording intervals are possible.

The system displays the CPTu data in real time and records the following parameters to a storage media during penetration:

- Depth
- Uncorrected tip resistance (q<sub>c</sub>)
- Sleeve friction (f<sub>s</sub>)
- Dynamic pore pressure (u)
- Additional sensors such as resistivity, passive gamma, ultra violet induced fluorescence, if applicable

All testing is performed in accordance to ConeTec's CPTu operating procedures which are in general accordance with the current ASTM D5778 standard.

Prior to the start of a CPTu sounding a suitable cone is selected, the cone and data acquisition system are powered on, the pore pressure system is saturated with silicone oil and the baseline readings are recorded with the cone hanging freely in a vertical position.

The CPTu is conducted at a steady rate of two centimeters per second, within acceptable tolerances. Typically one meter length rods with an outer diameter of 1.5 inches (38.1 millimeters) are added to advance the cone to the sounding termination depth. After cone retraction final baselines are recorded.

Additional information pertaining to ConeTec's cone penetration testing procedures:

- Each filter is saturated in silicone oil under vacuum pressure prior to use
- Baseline readings are compared to previous readings
- Soundings are terminated at the client's target depth or at a depth where an obstruction is encountered, excessive rod flex occurs, excessive inclination occurs, equipment damage is likely to take place, or a dangerous working environment arises
- Differences between initial and final baselines are calculated to ensure zero load offsets have not occurred and to ensure compliance with ASTM standards

The interpretation of piezocone data for this report is based on the corrected tip resistance  $(q_t)$ , sleeve friction  $(f_s)$  and pore water pressure (u). The interpretation of soil type is based on the correlations developed by Robertson et al. (1986) and Robertson (1990, 2009). It should be noted that it is not always possible to accurately identify a soil behavior type based on these parameters. In these situations, experience, judgment and an assessment of other parameters may be used to infer soil behavior type.

The recorded tip resistance  $(q_c)$  is the total force acting on the piezocone tip divided by its base area. The tip resistance is corrected for pore pressure effects and termed corrected tip resistance  $(q_t)$  according to the following expression presented in Robertson et al. (1986):

$$q_t = q_c + (1-a) \bullet u_2$$

where: qt is the corrected tip resistance

- q<sub>c</sub> is the recorded tip resistance
- u<sub>2</sub> is the recorded dynamic pore pressure behind the tip (u<sub>2</sub> position)
- a is the Net Area Ratio for the piezocone (0.8 for ConeTec probes)

The sleeve friction ( $f_s$ ) is the frictional force on the sleeve divided by its surface area. As all ConeTec piezocones have equal end area friction sleeves, pore pressure corrections to the sleeve data are not required.

The dynamic pore pressure (u) is a measure of the pore pressures generated during cone penetration. To record equilibrium pore pressure, the penetration must be stopped to allow the dynamic pore pressures to stabilize. The rate at which this occurs is predominantly a function of the permeability of the soil and the diameter of the cone.

The friction ratio  $(R_f)$  is a calculated parameter. It is defined as the ratio of sleeve friction to the tip resistance expressed as a percentage. Generally, saturated cohesive soils have low tip resistance, high friction ratios and generate large excess pore water pressures. Cohesionless soils have higher tip resistances, lower friction ratios and do not generate significant excess pore water pressure.

A summary of the CPTu soundings along with test details and individual plots are provided in the appendices. A set of files with calculated geotechnical parameters were generated for each sounding based on published correlations and are provided in Excel format in the data release folder. Information regarding the methods used is also included in the data release folder.

For additional information on CPTu interpretations and calculated geotechnical parameters, refer to Robertson et al. (1986), Lunne et al. (1997), Robertson (2009), Mayne (2013, 2014) and Mayne and Peuchen (2012).

The cone penetration test is halted at specific depths to carry out pore pressure dissipation (PPD) tests, shown in Figure PPD-1. For each dissipation test the cone and rods are decoupled from the rig and the data acquisition system measures and records the variation of the pore pressure (u) with time (t).

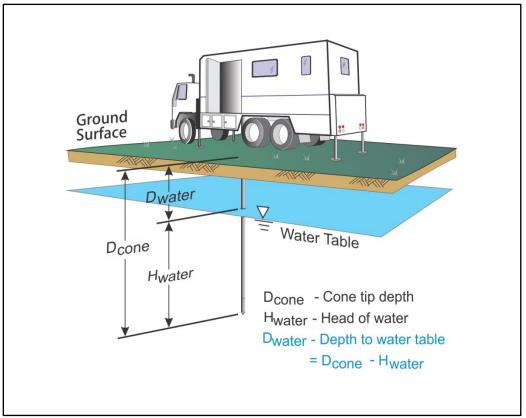

Figure PPD-1. Pore pressure dissipation test setup

Pore pressure dissipation data can be interpreted to provide estimates of ground water conditions, permeability, consolidation characteristics and soil behavior.

The typical shapes of dissipation curves shown in Figure PPD-2 are very useful in assessing soil type, drainage, in situ pore pressure and soil properties. A flat curve that stabilizes quickly is typical of a freely draining sand. Undrained soils such as clays will typically show positive excess pore pressure and have long dissipation times. Dilative soils will often exhibit dynamic pore pressures below equilibrium that then rise over time. Overconsolidated fine-grained soils will often exhibit an initial dilatory response where there is an initial rise in pore pressure before reaching a peak and dissipating.

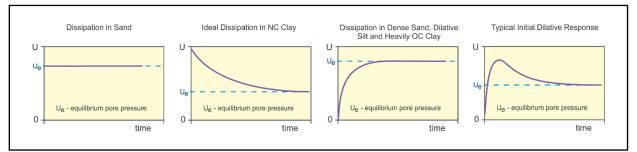

Figure PPD-2. Pore pressure dissipation curve examples

In order to interpret the equilibrium pore pressure  $(u_{eq})$  and the apparent phreatic surface, the pore pressure should be monitored until such time as there is no variation in pore pressure with time as shown for each curve in Figure PPD-2.

In fine grained deposits the point at which 100% of the excess pore pressure has dissipated is known as  $t_{100}$ . In some cases this can take an excessive amount of time and it may be impractical to take the dissipation to  $t_{100}$ . A theoretical analysis of pore pressure dissipations by Teh and Houlsby (1991) showed that a single curve relating degree of dissipation versus theoretical time factor (T\*) may be used to calculate the coefficient of consolidation ( $c_h$ ) at various degrees of dissipation resulting in the expression for  $c_h$  shown below.

$$c_h = \frac{T^* \cdot a^2 \cdot \sqrt{I_r}}{t}$$

Where:

- T\* is the dimensionless time factor (Table Time Factor)
- a is the radius of the cone
- Ir is the rigidity index
- t is the time at the degree of consolidation

Table Time Factor	. T* versus degree of dissipat	ion (Teh and Houlsby (1991))
-------------------	--------------------------------	------------------------------

Degree of Dissipation (%)	20	30	40	50	60	70	80
T* (u <sub>2</sub> )	0.038	0.078	0.142	0.245	0.439	0.804	1.60

The coefficient of consolidation is typically analyzed using the time ( $t_{50}$ ) corresponding to a degree of dissipation of 50% ( $u_{50}$ ). In order to determine  $t_{50}$ , dissipation tests must be taken to a pressure less than  $u_{50}$ . The  $u_{50}$  value is half way between the initial maximum pore pressure and the equilibrium pore pressure value, known as  $u_{100}$ . To estimate  $u_{50}$ , both the initial maximum pore pressure and  $u_{100}$  must be known or estimated. Other degrees of dissipations may be considered, particularly for extremely long dissipations.

At any specific degree of dissipation the equilibrium pore pressure (u at  $t_{100}$ ) must be estimated at the depth of interest. The equilibrium value may be determined from one or more sources such as measuring the value directly ( $u_{100}$ ), estimating it from other dissipations in the same profile, estimating the phreatic surface and assuming hydrostatic conditions, from nearby soundings, from client provided information, from site observations and/or past experience, or from other site instrumentation.

For calculations of  $c_h$  (Teh and Houlsby (1991)),  $t_{50}$  values are estimated from the corresponding pore pressure dissipation curve and a rigidity index (I<sub>r</sub>) is assumed. For curves having an initial dilatory response in which an initial rise in pore pressure occurs before reaching a peak, the relative time from the peak value is used in determining  $t_{50}$ . In cases where the time to peak is excessive,  $t_{50}$  values are not calculated.

Due to possible inherent uncertainties in estimating  $I_r$ , the equilibrium pore pressure and the effect of an initial dilatory response on calculating  $t_{50}$ , other methods should be applied to confirm the results for  $c_h$ .

Additional published methods for estimating the coefficient of consolidation from a piezocone test are described in Burns and Mayne (1998, 2002), Jones and Van Zyl (1981), Robertson et al. (1992) and Sully et al. (1999).

A summary of the pore pressure dissipation tests and dissipation plots are presented in the relevant appendix.

Full flow penetration testing (BCPTu) is performed in conjunction with a piezocone penetration test using an integrated electronic piezocone with a spherical attachment and a data acquisition system manufactured by Adara Systems Ltd., a subsidiary of ConeTec.

ConeTec's piezocone penetrometers are compression type designs in which the tip and friction sleeve load cells are independent and have separate load capacities. The piezocones use strain gauged load cells for tip and sleeve friction and a strain gauged diaphragm type transducer for recording pore pressure. The piezocones also have a platinum resistive temperature device (RTD) for monitoring the temperature of the sensors, an accelerometer type dual axis inclinometer and a geophone sensor for recording seismic signals. All signals are amplified downhole within the cone body and the analog signals are sent to the surface through a shielded cable.

ConeTec penetrometers are manufactured with various tip, friction and pore pressure capacities in 5 cm<sup>2</sup>, 10 cm<sup>2</sup> and 15 cm<sup>2</sup> tip base area configurations in order to maximize signal resolution for various soil conditions. The 15 cm<sup>2</sup> penetrometers do not require friction reducers as they have a diameter larger than the deployment rods. The 5 cm<sup>2</sup> and 10 cm<sup>2</sup> piezocones use a friction reducer consisting of a rod adapter extension behind the main cone body with an enlarged cross-sectional area (typically forty-four millimeter diameter over a length of thirty-two millimeters with tapered leading and trailing edges) located at a distance of 585 millimeters above the cone tip.

The penetrometers are designed with equal end area friction sleeves, a net end area ratio of 0.8 and cone tips with a sixty-degree apex angle.

The piezocone penetrometers are manufactured with dimensions, tolerances and sensor characteristics that are in general accordance with the current ASTM D5778 standard. ConeTec's calibration criteria also meet or exceed those of the current ASTM D5778 standard.

For ball full flow penetration tests, the cone tip is replaced with a spherical attachment that can have projected plan areas of  $40 \text{ cm}^2$ ,  $60 \text{ cm}^2$ ,  $100 \text{ cm}^2$  or  $150 \text{ cm}^2$ . The selection of the size is based on soil strength and deployment limitations. An illustration of the piezocone with a spherical attachment is presented in Figure BCPTu.

The specific piezocone and ball area used for each test is described in the ball full flow penetration test summary presented in the relevant appendix.

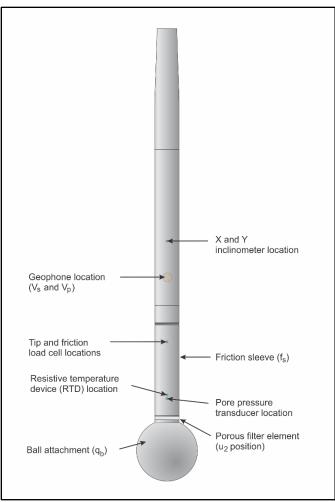

Figure BCPTu. Piezocone penetrometer with a spherical attachment

The ConeTec data acquisition systems consist of a Windows based computer and a signal conditioner and power supply interface box with a sixteen-bit (or greater) analog to digital (A/D) converter. The data is recorded in fixed depth increments using a depth wheel attached to the push cylinders or by using a spring loaded rubber depth wheel that is held against the cone rods. The typical recording interval is 2.5 centimeters; custom recording intervals are possible.

The system displays the data in real time and records the following parameters to a storage media during penetration:

- Depth
- Uncorrected ball tip resistance (q<sub>b</sub>)
- Sleeve friction (f<sub>s</sub>)
- Dynamic pore pressure (u) at the shoulder (u<sub>2</sub>) or at the equator of the ball
- Additional sensors such as resistivity, passive gamma, ultra violet induced fluorescence, if applicable

Prior to the start of a BCPTu sounding a suitable cone and spherical attachment are selected, the cone and data acquisition system are powered on, the pore pressure system is saturated with silicone oil and the baseline readings are recorded with the ball hanging freely in a vertical position.

The BCPTu is conducted at a steady rate of two centimeters per second, within acceptable tolerances. Typically, one-meter length rods with an outer diameter of 38.1 millimeters are added to advance the ball to the sounding termination depth. The test may be interrupted at selected depths to cycle the probe up and down in order to achieve a completely remolded soil state. Cycling is typically conducted during retraction of the ball and the number of conducted cycles is dependent on reaching a consistent tip value. After ball retraction the final baselines are recorded.

The full flow penetration test can be halted at specific depths to carry out pore pressure dissipation (PPD) tests. For each dissipation test the data acquisition system measures and records the variation of the pore pressure (u) with time (t). Pore pressure dissipation data can be interpreted to provide estimates of equilibrium pore pressures ( $u_{eq}$ ).

Additional information pertaining to ConeTec's full flow penetration testing procedures:

- Each filter is saturated in silicone oil under vacuum pressure prior to use
- Recorded baselines are checked with an independent multi-meter
- Baseline readings are compared to previous readings verifying compliance with ASTM standards
- Soundings are terminated at the client's target depth or at a depth where an obstruction is encountered, excessive rod flex occurs or excessive inclination occurs, equipment damage is likely to take place or a dangerous working environment arises
- Differences between initial and final baselines are calculated to ensure zero load offsets have not occurred and to ensure compliance with ASTM standards

Full flow penetration tests are conducted to assess the undrained shear strength (Su) of low to medium strength soils. During penetration, the soil flows around the penetrometer significantly reducing the influence of overburden stress as compared to the cone penetration test (CPTu). For the test to be valid, the soil must flow around the penetrometer. Cycling is conducted in order to achieve a completely remolded soil state to provide an indication of sensitivity in soft soils.

The recorded ball tip resistance  $(q_b)$  is the total force acting on the piezocone spherical attachment divided by its base area. The ball tip resistance is corrected for pore pressure effects and termed corrected ball tip resistance  $(q_{bt})$  according to the following expression:

$$q_{bt} = q_b + [(1-a)u_2] \frac{A_s}{A_p}$$

where: q<sub>bt</sub> is the corrected ball tip resistance

q<sub>b</sub> is the recorded ball tip resistance

u<sub>2</sub> is the recorded dynamic pore pressure behind the tip (u<sub>2</sub> position)

a is the Net Area Ratio for the piezocone (0.8 for ConeTec probes)

A<sub>s</sub> is the shaft area

 $A_{\mbox{\scriptsize p}}$  is the ball plan area

The undrained shear strength (Su) derived from the full flow penetration test is related to the net ball tip resistance ( $q_{btnet}$ ) and ball factor ( $N_{ball}$ ) using the following relationship:

$$Su = \frac{q_{btnet}}{N_{ball}}$$

Due to different geometry and the subdued sleeve and pore pressure response, full flow penetration test results are not used for the interpretation of other geotechnical parameters or for soil classification.

A summary of the BCPTu soundings along with test details and individual plots are provided in the appendices. Tabular results generated for each sounding are provided in Excel format in the data release folder. Information regarding the calculated parameters is also included in the data release folder.

For additional information on full flow penetrometer testing, refer to Weemees et al. (2006).

The electric field vane system is manufactured by Adara Systems Ltd., a subsidiary of ConeTec. An illustration of the uphole vane system configuration is presented in Figure eVST.

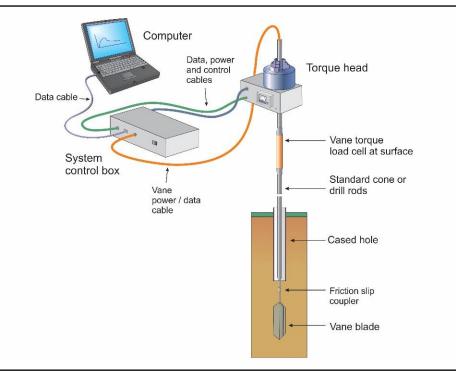

Figure eVST. Illustration of the uphole electric field vane system configuration

The vane system is designed with an array of strain gauges in a load cell that measure the applied torque. The torque signal is amplified and converted to digital data within the tool and transmitted to the data acquisition system through a shielded cable. The system uses a friction slip coupler to permit the free slip or play of approximately fifteen degrees between the rods and the vane blade in order to isolate and record rod friction from the soil before rotation of the vane blade starts. The system is designed to use vane blades of various sizes and configurations that connect to the friction slip coupler. The vane blades manufactured by Adara have dimensions and tolerances that are in general accordance with the current ASTM D2573 standards. In very soft soil conditions and at the request of the client, ConeTec may use a large diameter vane blade that exceeds the ASTM D2573 maximum size specifications in order to maximize torque resolution. In very stiff soil conditions and at the request of the client, ConeTec may use a smaller diameter vane blade than the minimum size specified in ASTM D2573 in order to obtain a peak torque below the capacity of the load cell.

The electric motor (capable of 100 Newton-meters of torque) is designed to clamp onto and rotate the rods and vane blade at a constant rate.

ConeTec's calibration criteria of the load cells are in accordance with the current ASTM D2573 standard.

The data acquisition system consists of a computer that records the vane data every 0.2 degrees of rotation. The system records the following parameters and saves them to a file as the test is conducted:

- Torque in Newton-meters
- Rotation in degrees
- Elapsed time in seconds (from the start of the test)

All testing is performed in accordance to ConeTec's field vane testing operating procedures and in general accordance with the current ASTM D2573 standard. For additional information on vane shear testing refer to Greig et al. (1987).

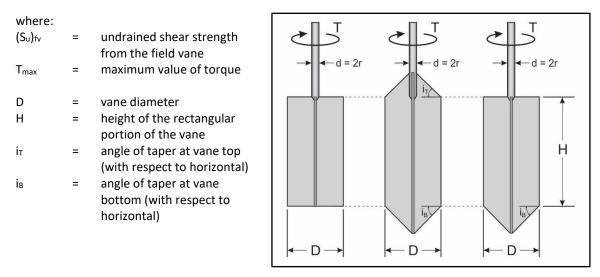

Prior to the start of a vane shear test profile, a suitable sized vane blade is selected, the vane system is powered on and the vane load cell baseline reading is recorded with the load cell hanging freely in a vertical position.

The vane blade, slip coupler and rods are advanced to the desired test depth through a cased hole, typically using AWJ drill rods or one-meter length rods with an outer diameter of 1.5 inches (38.1 millimeters). Test depths are referenced to the middle of the rectangular portion of the vane blade. The motor rotates the rods at a near constant rate up to and beyond the yield stress (peak) until the load remains near constant (post peak). Following post peak readings, the vane blade is then rapidly rotated clockwise ten times to completely remold the soil. The test procedure is repeated in order to record the remolded strength of the soil. The vane blade is then advanced to the next depth and the procedure is repeated or the vane blade is retracted to allow for drilling and vane blade size changes. Once the vane profile is complete, the final baseline of the load cell is recorded and compared to previous reading as a QA/QC check.

Undrained shear strength from the field vane,  $(S_u)_{fv}$ , is calculated from torque measurements using the following general equation (ASTM D2573) taking into consideration the case of rectangular or tapered ends at the top and/or bottom of the vane blade.

$$(S_u)_{fv} = \frac{12 \cdot T_{max}}{\pi D^2 \left(\frac{D}{\cos(i_T)} + \frac{D}{\cos(i_B)} + 6H\right)}$$

For rectangular vane blades where H/D = 2, the above equation simplifies to:

$$(S_u)_{fv} = \frac{6 \cdot T_{max}}{7\pi D^3}$$

The recorded rod friction is subtracted from the peak and remolded torque. No correction factors are applied to the vane results to derive the mobilized shear strength ( $\tau_{mobilized}$ ).

A summary of the vane shear tests, a table of results and individual VST plots are provided in the relevant appendices. Tabular data in Excel format is provided in the data release folder.

1. Coordinates were provided by client

2. Coordinates currently not available. Corrdiantes will be proviced by client at a later date

3. Test depth reference depth below mudline.

4. All vane tests were completed from the floating barge platform. The vane test results were affected by barge movement from local waves, local vessel traffic and river flow. Additionally, the vane results were susceptible to elevation charge from either rising or falling tide. Over the course of a vane test the barge would gain/lose approximately 1"-4" of elevation due to tidal effects.

Attachment G.2 Geotechnical Laboratory Testing

July 19, 2022

Anchor QEA, LLC. 1201 3<sup>rd</sup> Avenue, Suite 2600 Seattle, WA 98101

To Whom It May Concern,

MTC approves and authorizes the release and publication of statements, conclusions, and extracts from or regarding our reports to Anchor QEA, LLC.

If you have any other questions, feel free to call us at (360) 755-1990, or email me at <u>alex.eifrig@mtc-inc.net</u>.

Thank you,

Alex Eifrig

MATERIALS TESTING & CONSULTING, INC. Alex Eifrig NW Region Laboratory Manager WABO Supervising Laboratory Technician

Client:	Anchor QEA	Date:	September 23, 2021
Address:	21328 2nd Drive SE	Project:	Q.C Lower Duwamish Waterway
	Bothell, WA 98021	Project #:	21B233
Attn:	Garrett Timm	Sample #:	B21-1427 - 1446
<b>Revised on:</b>		Date sampled:	7-7-21 & 7-8-21

As requested MTC, Inc. has performed the following test(s) on the sample referenced above. The testing was performed in accordance with current applicable AASHTO or ASTM standards as indicated below. The results obtained in our laboratory were as follows below or on the attached pages:

	Test(s) Performed:	Test Results		Test(s) Performed:	Test Results
X	Sieve Analysis	Please See Attached Reports		Sulfate Soundness	
	Proctor			Bulk Density & Voids	
	Sand Equivalent			WSDOT Degradation	
	Fracture Count			LA Abrasion	
Χ	Moisture Content	Please See Attached Report	Х	Direct Shear	Please See Attached Reports
	Specific Gravity, Coarse		Х	Specific Gravity, Soils	Please See Attached Reports
	Specific Gravity, Fine				
Χ	Hydrometer Analysis	Please See Attached Reports			
Х	Atterberg Limits	Please See Attached Reports			

If you have any questions concerning the test results, the procedures used, or if we can be of any further assistance please call on us at the number below.

Aladet an

Respectfully Submitted, Meghan Blodgett-Carrillo WABO Supervising Laboratory Technician

Comments: Liquid limit cannot be established as the material displays rapid dilation upon spreading into the cup. At lower moistures the material does not spread into the liquid limit cup without tearing the soil cake. Plastic limit cannot be determined as the material does not roll down to 1/8" threads before cracking or crumbling. Non-plastic.

<b>Revised on:</b>		Date sampled:	7-26-21 & 7-27-21

As requested MTC, Inc. has performed the following test(s) on the sample referenced above. The testing was performed in accordance with current applicable AASHTO or ASTM standards as indicated below. The results obtained in our laboratory were as follows below or on the attached pages:

	Test(s) Performed:	Test Results		Test(s) Performed:	Test Results
X	Sieve Analysis	Please See Attached Reports		Sulfate Soundness	
	Proctor			Bulk Density & Voids	
	Sand Equivalent			WSDOT Degradation	
	Fracture Count			LA Abrasion	
Χ	Moisture Content	Please See Attached Report	Х	Direct Shear	Please See Attached Reports
	Specific Gravity, Coarse		X	Specific Gravity, Soils	Please See Attached Reports
	Specific Gravity, Fine				
Χ	Hydrometer Analysis	Please See Attached Reports			
Χ	Atterberg Limits	Please See Attached Reports			

If you have any questions concerning the test results, the procedures used, or if we can be of any further assistance please call on us at the number below.

#### ASTM D4318 - Liquid Limit, Plastic Limit and Plasticity Index of Soils

Comments: Liquid limit cannot be established as the material displays rapid dilation upon spreading into the cup. At lower moistures the material does not spread into the liquid limit device without tearing the soil cake. Plastic limit cannot be determined as the material does not roll down to 1/8" threads before cracking or crumbling. Non-plastic.

Client:	Anchor QEA	Date:	September 29, 2021
Address:	21328 2nd Drive SE	Project:	Q.C Lower Duwamish Waterway
	Bothell, WA 98021	Project #:	21B233
Attn:	Garrett Timm	Sample #:	B21-1447 - 1466
<b>Revised on:</b>		Date sampled:	7-8-21 & 7-9-21

As requested MTC, Inc. has performed the following test(s) on the sample referenced above. The testing was performed in accordance with current applicable AASHTO or ASTM standards as indicated below. The results obtained in our laboratory were as follows below or on the attached pages:

	Test(s) Performed:	Test Results		Test(s) Performed:	Test Results
X	Sieve Analysis	Please See Attached Reports		Sulfate Soundness	
	Proctor			Bulk Density & Voids	
	Sand Equivalent			WSDOT Degradation	
	Fracture Count			LA Abrasion	
Χ	Moisture Content	Please See Attached Report	Χ	Direct Shear	Please See Attached Reports
	Specific Gravity, Coarse		Χ	Specific Gravity, Soils	Please See Attached Reports
	Specific Gravity, Fine				
Χ	Hydrometer Analysis	Please See Attached Reports			
Χ	Atterberg Limits	Please See Attached Reports			

If you have any questions concerning the test results, the procedures used, or if we can be of any further assistance please call on us at the number below.

## ASTM D4318 - Liquid Limit, Plastic Limit and Plasticity Index of Soils

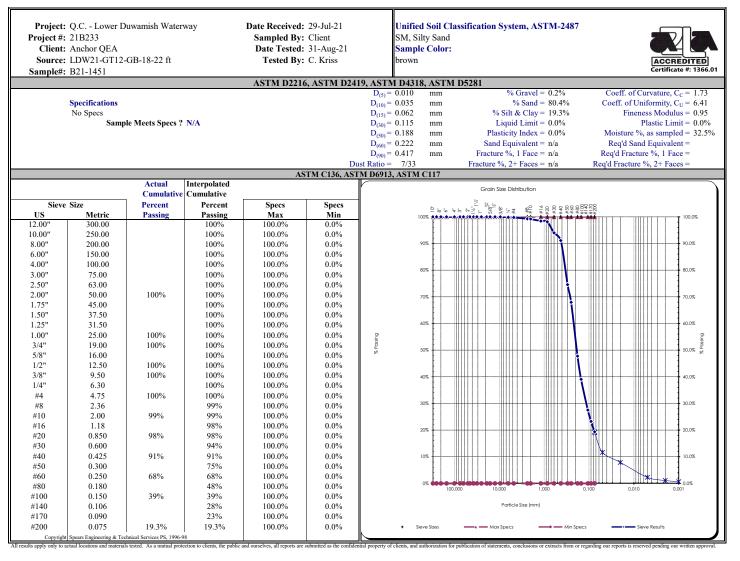

Comments: Liquid limit cannot be established as the material displays rapid dilation upon spreading into the cup. At lower moistures the material does not spread into the cup without tearing the soil cake. Plastic limit cannot be determined as the material does not roll down to 1/8" threads before cracking or crumbling. Non-plastic.

As requested MTC, Inc. has performed the following test(s) on the sample referenced above. The testing was performed in accordance with current applicable AASHTO or ASTM standards as indicated below. The results obtained in our laboratory were as follows below or on the attached pages:

	Test(s) Performed:	Test Results		Test(s) Performed:	Test Results
x	Sieve Analysis	Please See Attached Reports		Sulfate Soundness	
	Proctor			Bulk Density & Voids	
	Sand Equivalent			WSDOT Degradation	
	Fracture Count			LA Abrasion	
Χ	Moisture Content	Please See Attached Report	Х	Direct Shear	Please See Attached Reports
	Specific Gravity, Coarse		X	Specific Gravity, Soils	Please See Attached Reports
	Specific Gravity, Fine				
Χ	Hydrometer Analysis	Please See Attached Reports			
Χ	Atterberg Limits	Please See Attached Reports			

If you have any questions concerning the test results, the procedures used, or if we can be of any further assistance please call on us at the number below.

## ASTM D4318 - Liquid Limit, Plastic Limit and Plasticity Index of Soils

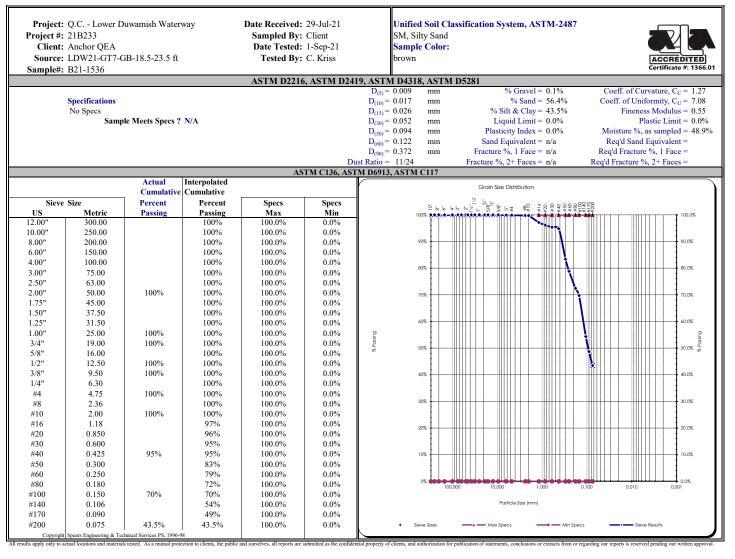

All results apply only to actual locations and mat reports is reserved pending our written approval.

Plastic limit cannot be determined as the material does not roll down to 1/8" threads before cracking or crumbling. Non-plastic Comments:

### ASTM D4318 - Liquid Limit, Plastic Limit and Plasticity Index of Soils

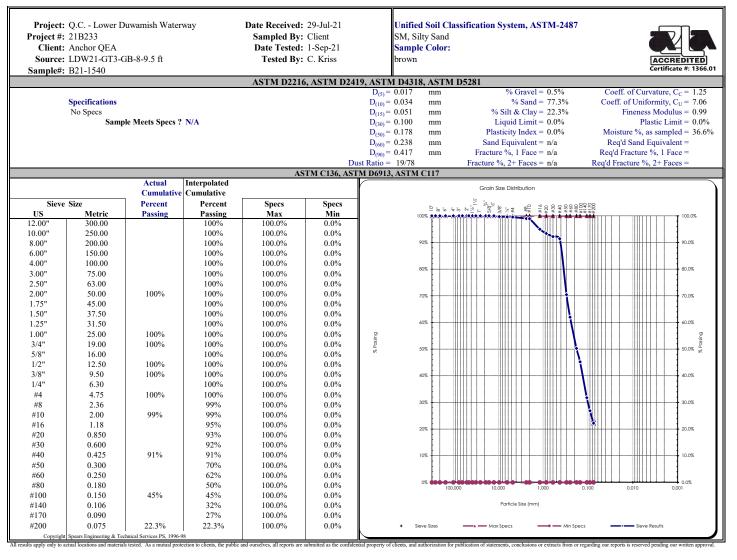

All results apply only to actual locations and materials tested. As a mutual protection to clients, the public and ourselves, all reports are submitted as the confidential property of clients, and authorization for publication of statements, conclusions or extracts from or regarding our reports is reserved pending our written approval.

Comments: Liquid limit cannot be established as the material displays rapid dilation upon spreading into the cup. At lower moistures the material does not spread into the liquid limit device without tearing the soil cake. Plastic limit cannot be determined as the material does not roll down to 1/8" threads before cracking or crumbling. Non-plastic.

### ASTM D4318 - Liquid Limit, Plastic Limit and Plasticity Index of Soils

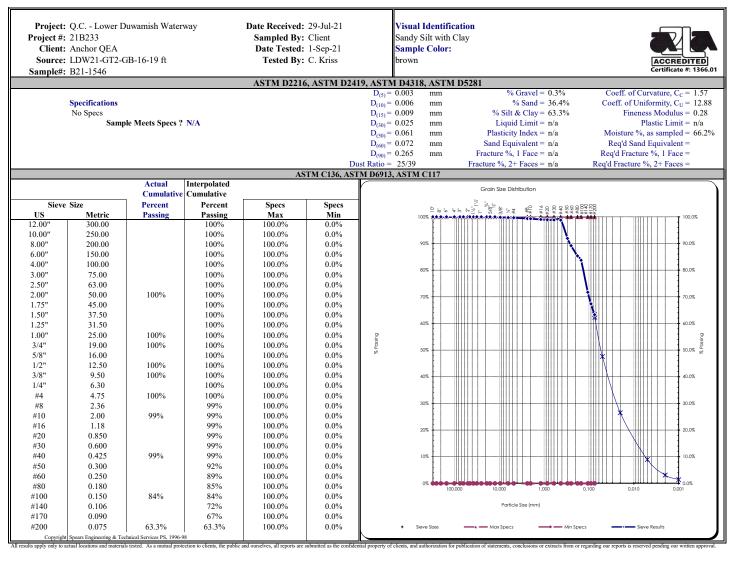

All results apply only to actual locations and materials tested. As a mutual protection to clients, the public and ourselves, all reports are submitted as the confidential property of clients, and authorization for publication of statements, conclusions or extracts from or regarding our reports is reserved pending our written approval.

Comments: Liquid limit cannot be established as the material displays rapid dilation upon spreading into the cup. At lower moistures the material does not spread into the liquid limit device without tearing the soil cake. Plastic limit cannot be determined as the material does not roll down to 1/8" threads before cracking or crumbling. Non-plastic.

<b>Revised on:</b>		Date sampled:	7-12-21 & 7-13-21

As requested MTC, Inc. has performed the following test(s) on the sample referenced above. The testing was performed in accordance with current applicable AASHTO or ASTM standards as indicated below. The results obtained in our laboratory were as follows below or on the attached pages:

	Test(s) Performed:	Test Results		Test(s) Performed:	Test Results
X	Sieve Analysis	Please See Attached Reports		Sulfate Soundness	
	Proctor			Bulk Density & Voids	
	Sand Equivalent			WSDOT Degradation	
	Fracture Count			LA Abrasion	
Χ	Moisture Content	Please See Attached Report	Х	Direct Shear	Please See Attached Reports
	Specific Gravity, Coarse		Х	Specific Gravity, Soils	Please See Attached Reports
	Specific Gravity, Fine				
Χ	Hydrometer Analysis	Please See Attached Reports			
Х	Atterberg Limits	Please See Attached Reports			

If you have any questions concerning the test results, the procedures used, or if we can be of any further assistance please call on us at the number below.

# ASTM D4318 - Liquid Limit, Plastic Limit and Plasticity Index of Soils

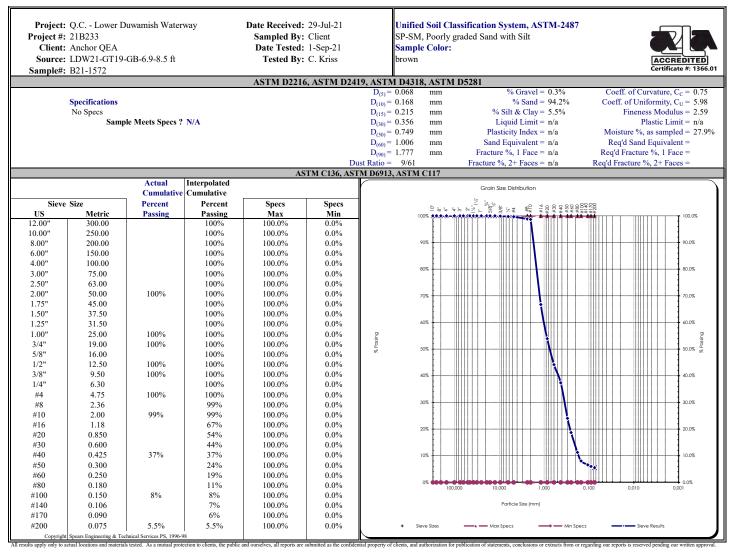

All results apply only to actual locations and mat reports is reserved pending our written approval.

Comments: Liquid limit cannot be established as the material displays rapid dilation upon spreading into the cup. At lower moistures the material does not spread into the liquid limit cup without tearing the soil cake. Plastic limit cannot be determined as the material does not roll down to 1/8" threads before cracking or crumbling. Non-plastic.

As requested MTC, Inc. has performed the following test(s) on the sample referenced above. The testing was performed in accordance with current applicable AASHTO or ASTM standards as indicated below. The results obtained in our laboratory were as follows below or on the attached pages:

	Test(s) Performed:	Test Results		Test(s) Performed:	Test Results
X	Sieve Analysis	Please See Attached Reports		Sulfate Soundness	
	Proctor			Bulk Density & Voids	
	Sand Equivalent			WSDOT Degradation	
	Fracture Count			LA Abrasion	
Χ	Moisture Content	Please See Attached Report	Х	Direct Shear	Please See Attached Reports
	Specific Gravity, Coarse		Х	Specific Gravity, Soils	Please See Attached Reports
	Specific Gravity, Fine				
Χ	Hydrometer Analysis	Please See Attached Reports			
Х	Atterberg Limits	Please See Attached Reports			

If you have any questions concerning the test results, the procedures used, or if we can be of any further assistance please call on us at the number below.

# ASTM D4318 - Liquid Limit, Plastic Limit and Plasticity Index of Soils

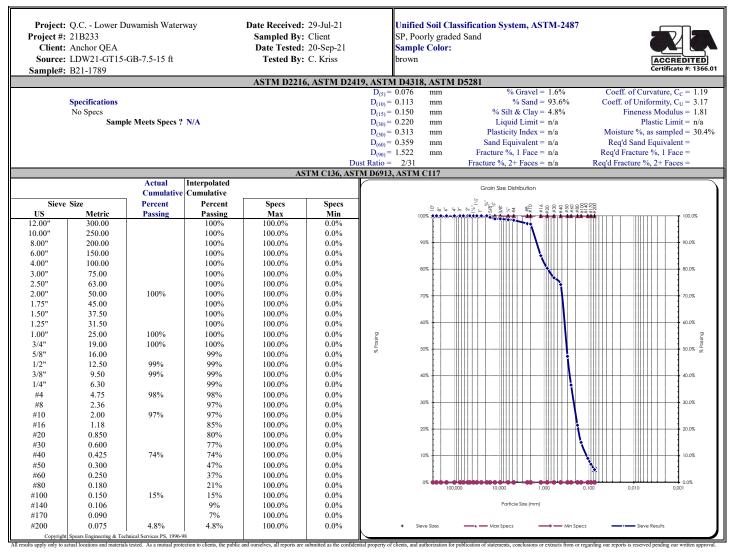

Comments: Liquid limit cannot be established as the material displays rapid dilation upon spreading into the cup. At lower moistures the material does not spread into the liquid limit cup without tearing the soil cake. Plastic limit cannot be determined as the material does not roll down to 1/8" threads before cracking or crumbling. Non-plastic.

As requested MTC, Inc. has performed the following test(s) on the sample referenced above. The testing was performed in accordance with current applicable AASHTO or ASTM standards as indicated below. The results obtained in our laboratory were as follows below or on the attached pages:

	Test(s) Performed:	Test Results		Test(s) Performed:	Test Results
X	Sieve Analysis	Please See Attached Reports		Sulfate Soundness	
	Proctor			Bulk Density & Voids	
	Sand Equivalent			WSDOT Degradation	
	Fracture Count			LA Abrasion	
Χ	Moisture Content	Please See Attached Report	Х	Direct Shear	Please See Attached Reports
	Specific Gravity, Coarse		Х	Specific Gravity, Soils	Please See Attached Reports
	Specific Gravity, Fine				
Χ	Hydrometer Analysis	Please See Attached Reports			
Х	Atterberg Limits	Please See Attached Reports			

If you have any questions concerning the test results, the procedures used, or if we can be of any further assistance please call on us at the number below.

our reports is reserved pending our written approval.

Comments: Liquid limit cannot be established as the material displays rapid dilation. At lower moistures the material does not spread into the liquid limit device without tearing the soil cake. Plastic limit cannot be determined as the sample does not roll down to 1/8" threads before cracking or crumbling. Non-plastic.

<b>Revised on:</b>		Date sampled:	July 16, 2021

As requested MTC, Inc. has performed the following test(s) on the sample referenced above. The testing was performed in accordance with current applicable AASHTO or ASTM standards as indicated below. The results obtained in our laboratory were as follows below or on the attached pages:

	Test(s) Performed:	Test Results		Test(s) Performed:	Test Results
X	Sieve Analysis	Please See Attached Reports		Sulfate Soundness	
	Proctor			Bulk Density & Voids	
	Sand Equivalent			WSDOT Degradation	
	Fracture Count			LA Abrasion	
Χ	Moisture Content	Please See Attached Report	Х	Direct Shear	Please See Attached Reports
	Specific Gravity, Coarse		Х	Specific Gravity, Soils	Please See Attached Reports
	Specific Gravity, Fine				
Χ	Hydrometer Analysis	Please See Attached Reports			
Χ	Atterberg Limits	Please See Attached Reports			

If you have any questions concerning the test results, the procedures used, or if we can be of any further assistance please call on us at the number below.

### ASTM D4318 - Liquid Limit, Plastic Limit and Plasticity Index of Soils

in reason apply any to accum contention and materials reason. For a material processon to enterior, we prove and outserver, an report at submitted as the connecting property of example, and automation for providential of materials out reports is reserved pending our written approval.

Comments: Liquid limit cannot be determined as the material displays rapid dilation. At lower moistures the sample does not spread into the cup without tearing the soil cake. Unable to establish plastic limit as the material does not roll down to 1/8" threads before cracking or crumbling. Non-plastic.

October 19, 2021 HWA Project No. 2012-002-23 Task 51

Materials Testing & Consulting, Inc. 777 Chrysler Drive Burlington, WA 98233

Attention: Ms. Meghan Blodgett-Carrillo

Subject: LABORATORY TESTING REPORT QC - Lower Duwamish Waterway MTC Project Number: 21B233

Dear Ms. Blodgett-Carrillo;

In accordance with your request, HWA GeoSciences Inc. (HWA) performed laboratory testing for the above referenced project. Herein we present the results of our laboratory analyses, which are summarized on the attached Figures. The laboratory testing program was performed in general accordance with your instructions and appropriate ASTM Standards as outlined below.

**SAMPLE DESCRIPTION:** The subject samples were delivered to our laboratory on August 26, 2021 by MTC personnel. The samples were delivered in four Shelby tubes and were designated with exploration ID and depth of sampling. The soil samples were classified using visual-manual methods. The descriptions may be found on the attached Summary of Material Properties, Figure 1.

**MOISTURE CONTENT OF SOIL:** The moisture contents of the soil samples (percent by dry mass) were determined in general accordance with ASTM D2216. The results are shown on Figure 1.

**SPECIFIC GRAVITY OF SOILS:** The specific gravity of the selected samples was determined using method ASTM D854. The test results are shown on the attached Summary of Material Properties, Figure 1.

**LIQUID LIMIT, PLASTIC LIMIT, AND PLASTICITY INDEX OF SOILS (ATTERBERG LIMITS):** The plasticity index of each specified sample was tested using method ASTM D4318, multi-point method. The results are reported on the attached Liquid Limit, Plastic Limit, and Plasticity Index of Soils Report, Figure 2.

**CONSOLIDATED UNDRAINED TRIAXIAL COMPRESSION OF SOILS:** Selected samples were tested in general accordance with method ASTM D4767 to determine the shear strength characteristics of the soil. The samples were extruded from Shelby tubes, and the test specimens were trimmed to obtain a cylindrical test sample with a length to diameter ratio between 2:1 and 2.5:1. The specimens were carefully weighed and measured prior to testing.

Three trials were run at varying confining stresses specified by the client. Each sample was run using a single specimen to perform a multi-stage shear test.

The multi-stage method was performed by first consolidating the sample at the lowest specified confining pressure. The sample was then sheared until the change in pore pressure was at or near its estimated peak. After reaching the peak change in pore pressure, the shear phase was terminated, and the specimen was reconsolidated at the middle consolidation pressure. Under the second consolidation pressure the sample was again sheared until the change in pore pressure was at or near its estimated peak, at which point the shear was terminated. The sample was reconsolidated a third and final time under the highest confining pressure and shearing was performed to sample failure, concluding the test.

For sample LDW21-GT33-GB at 6.0-8.0', the test was terminated at 20.5% strain due to a spike in pore pressure caused by a perforation in the membrane encasing the sample. As a result, the final moisture content of the sample was affected due to the ingress of water from the surrounding water filled pressure cell. The final moisture content for this sample was determined to be 70.7%.

The Consolidated Undrained test results are summarized and plotted graphically in Figures 3-6.

**ONE DIMENSIONAL CONSOLIDATION PROPERTIES OF SOIL:** The consolidation properties of selected soil samples were measured in general accordance with ASTM D 2435. Saturation was maintained by inundation of the sample throughout the test. The samples were subjected to increasing increments of total stress, the duration of which was selected to exceed the time required for completion of primary consolidation as defined in the Standard, Method B. Unloading of the sample was carried out incrementally. The primary compression test results are presented on the attached Consolidation Test Reports, Figures 7-10.

October 19, 2021 HWA Project No. 2012-002-23 T51

**CLOSURE:** Experience has shown that test values on soil and other natural materials vary with each representative sample. As such, HWA has no knowledge as to the extent and quantity of material the tested samples may represent. HWA also makes no warranty as to how representative either the samples tested or the test results obtained are to actual field conditions. It is a well-established fact that sampling methods present varying degrees of disturbance that affect sample representativeness.

No copy should be made of this report except in its entirety.

We appreciate the opportunity to provide laboratory testing services on this project. Should you have any questions or comments, or if we may be of further service, please call.

Sincerely,

HWA GEOSCIENCES INC.

Greg Barker Materials Laboratory Supervisor

reports is reserved pending our written approval.

Comments: Liquid limit cannot be established as the material displays rapid dilation upon spreading into the cup. At lower moistures the material does not spread into the liquid limit device without tearing the soil cake. Plastic limit cannot be determined as the material does not roll down to 1/8" threads before cracking or crumblind. Non-plastic.

As requested MTC, Inc. has performed the following test(s) on the sample referenced above. The testing was performed in accordance with current applicable AASHTO or ASTM standards as indicated below. The results obtained in our laboratory were as follows below or on the attached pages:

	Test(s) Performed:	Test Results		Test(s) Performed:	Test Results
Х	Sieve Analysis	Please See Attached Reports		Sulfate Soundness	
	Proctor			Bulk Density & Voids	
	Sand Equivalent			WSDOT Degradation	
	Fracture Count			LA Abrasion	
Χ	Moisture Content	Please See Attached Report	X	Direct Shear	Please See Attached Reports
	Specific Gravity, Coarse		X	Specific Gravity, Soils	Please See Attached Reports
	Specific Gravity, Fine				
Χ	Hydrometer Analysis	Please See Attached Reports			
Χ	Atterberg Limits	Please See Attached Reports			

If you have any questions concerning the test results, the procedures used, or if we can be of any further assistance please call on us at the number below.

As requested MTC, Inc. has performed the following test(s) on the sample referenced above. The testing was performed in accordance with current applicable AASHTO or ASTM standards as indicated below. The results obtained in our laboratory were as follows below or on the attached pages:

	Test(s) Performed:	Test Results		Test(s) Performed:	Test Results
Х	Sieve Analysis	Please See Attached Reports		Sulfate Soundness	
	Proctor			Bulk Density & Voids	
	Sand Equivalent			WSDOT Degradation	
	Fracture Count			LA Abrasion	
Χ	Moisture Content	Please See Attached Report	Χ	Direct Shear	Please See Attached Reports
	Specific Gravity, Coarse		X	Specific Gravity, Soils	Please See Attached Reports
	Specific Gravity, Fine				
Χ	Hydrometer Analysis	Please See Attached Reports			
Χ	Atterberg Limits	Please See Attached Reports			

If you have any questions concerning the test results, the procedures used, or if we can be of any further assistance please call on us at the number below.

# ASTM D4318 - Liquid Limit, Plastic Limit and Plasticity Index of Soils

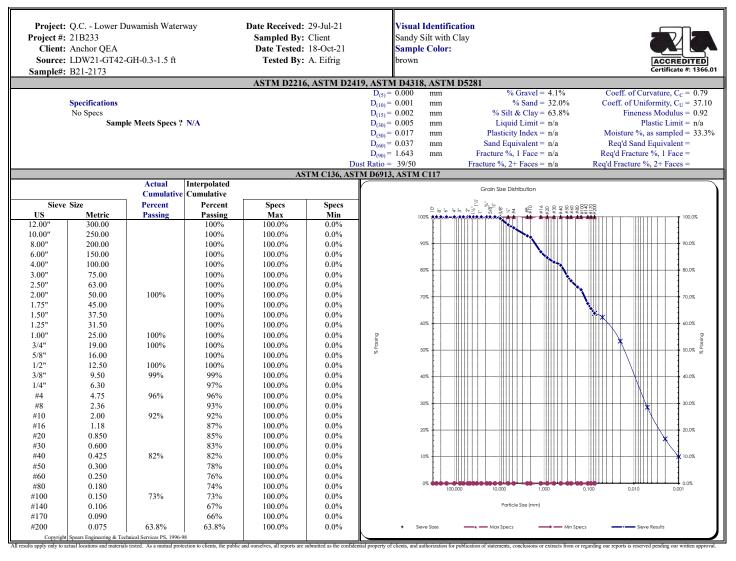

Comments: Liquid limit cannot be established as the material displays rapid dilation. At lower moistures the material does not spread into the cup without tearing the soil cake. Plastic limit cannot be determined as the sample does not roll down to 1/8" threads before cracking or crumbling. Non-plastic.
